

Package ‘HQM’

May 7, 2026

Type Package

Title Superefficient Estimation of Future Conditional Hazards Based on Marker Information

Version 2.1

Maintainer Dimitrios Bagkavos <dimitrios.bagkavos@gmail.com>

Description Provides univariate and indexed (multivariate) nonparametric smoothed kernel estimators for the future conditional hazard rate function when time-dependent covariates are present, a bandwidth selector for the estimator's implementation and pointwise and uniform confidence bands. Methods used in the package refer to Bagkavos, Isakson, Mammen, Nielsen and Proust-Lima (2025) <[doi:10.1093/biomet/asaf008](https://doi.org/10.1093/biomet/asaf008)>.

auc.hqm

AUC for the High Quality Marker estimator

Description

Calculates the AUC for the HQM estimator.

Usage

```
auc.hqm(xin, est, landm, th, event_time_name, status_name)
```

Arguments

| | |
|-----------------|---|
| xin | A data frame containing event times and the patient status. |
| est | The HQM estimator values, typically the output of get_h_x . |
| landm | Landmark time. |
| th | Time horizon. |
| event_time_name | The column name of the event times in the xin data frame. |
| status_name | The column name of the status variable in the xin frame. |

Details

The function [auc.hqm](#) implements the AUC calculation for the HQM estimator estimator.

Value

A vector of two values: the landmark time of the calculation and the AUC value.

See Also

[bs.hqm](#)

Examples

```
library(survival)
Landmark <- 2
pbcT1 <- pbc2[which(pbc2$year< Landmark & pbc2$years> Landmark),]
ls<-50 # 50 grid points to evaluate the estimates
s.out<- pbcT1[, 'year']
s.out.use <- seq(0, max(s.out), max(s.out)/( ls-1))

timesS2 <- seq(Landmark,14,by=0.5)
b=0.9
arg1<- get_h_x(pbcT1, 'albumin', br_s = s.out.use, event_time_name = 'years',
              time_name = 'year', event_name = 'status2', 2, 0.9)
br_s2 = seq(Landmark, 14, length=ls-1)
sfalb2<- make_sf( (br_s2[2]-br_s2[1])/4 , arg1)
tHor <- 1.5
auc.hq.use<-auc.hqm(pbcT1, sfalb2, Landmark,tHor,
                  event_time_name = 'years', status_name = 'status2')
auc.hq.use
```

 Boot.hqm

Indexed HQM hazard estimator for one bootstrap sample

Description

Compute the bootstrap estimate of the indexed HQM hazard estimate for a single (bootstrap) sample. The function is meant to be used internally for the calculation of confidence intervals

Usage

```
Boot.hqm(in.par, data, data.id, ls, X1, XX1, event_time_name = 'years',
         time_name = 'year', event_name = 'status2', b, t)
```

Arguments

| | |
|-----------------|--|
| in.par | Numeric vector, the values of the indexing parameters. |
| data | Bootstrap data.frame. |
| data.id | Id-level data.frame (result of to_id). |
| ls | user supplied grid length on the time_name argument. |
| X1 | List of vectors for indexing: each vector corresponds to a biomarker and contains one summary measurement per individual. |
| XX1 | List of vectors for indexing: each vector corresponds to a single biomarker and contains its longitudinal measurements across all individuals/time points. |
| event_time_name | Name of event time column. |
| time_name | Name of observation time column. |
| event_name | Name of event indicator column. |
| b | Bandwidth parameter. |
| t | Conditioning level. |

Value

Numeric vector with estimated hazard on the grid.

Examples

```
#Single instance of the bootstrap version of the bootstrap version
#of the indexed HQM estimator

b.alb = 0.9
b.bil = 4

t.alb = 1 # refers to zero mean variables - slightly high
t.bil = 1.9 # refers to zero mean variable - high
```

```

par.alb <- 0.0702 #0.149
par.bil <- 0.0856 #0.10

b = 0.42 # The result, on the indexed marker 'indmar' of
      #\code{b_selection(pbc2, 'indmar', 'years', 'year', 'status2', I=26, seq(0.2,0.4,by=0.01))}
t = t.alb * par.alb + t.bil *par.bil

marker_name1 <- 'albumin'
marker_name2 <- 'serBilir'
event_time_name <- 'years'
time_name <- 'year'
event_name <- 'status2'
id<-'id'
ls<-50

data.use<-pbc2
data.use.id<-to_id(data.use)
data.use.id<-data.use.id[complete.cases(data.use.id), ]

# mean adjust the data:
X1t=data.use[,marker_name1] -mean(data.use[, marker_name1])
XX1t=data.use.id[,marker_name1] -mean(data.use.id[, marker_name1])
X2t=data.use[,marker_name2] -mean(data.use[, marker_name2])
XX2t=data.use.id[,marker_name2] -mean(data.use.id[, marker_name2])

X1=list(X1t, X2t)
XX1=list(XX1t, XX2t)
boot.haz<-Boot.hqm (c(par.alb,par.bil), data.use, data.use.id, ls=ls, X1, XX1,
                    event_time_name = 'years', time_name = 'year', event_name = 'status2', b, t)

```

Boot.hrandindex.param *Bootstrap Estimation of Hazard Function and Index Parameters*

Description

Performs bootstrap estimation of hazard rates and corresponding index parameters for a given set of bootstrap samples. For each bootstrap replicate, the function re-estimates the index parameters via optimisation and computes hazard estimates using `Boot.hqm`. The output is used as input in functions `Quantile.Index.CIs` and `Pivot.Index.CIs`

Usage

```

Boot.hrandindex.param(B, Boot.samples, marker_name1, marker_name2, event_time_name,
                      time_name, event_name, b, t, true.haz, v.param, n.est.points)

```

Arguments

| | |
|-----------------|--|
| B | Integer. Number of bootstrap iterations. |
| Boot.samples | A list of bootstrap datasets. Each element corresponds to one replicate. |
| marker_name1 | Character string. Name of the first longitudinal marker. |
| marker_name2 | Character string. Name of the second longitudinal marker. |
| event_time_name | Name of the event time variable in the data. |
| time_name | Name of the time variable for the longitudinal marker measurements. |
| event_name | Name of the event indicator variable. |
| b | Numeric. Bandwidth parameter used in hazard estimation. |
| t | Numeric. Evaluation point for the conditional hazard. |
| true.haz | Numeric vector. The true or reference hazard used in the optimisation criterion. |
| v.param | Numeric vector. Starting values of the indexing parameters for the optimisation of the index coefficients. |
| n.est.points | Integer. Number of estimation grid points for the hazard curve. |

Details

For each bootstrap iteration $k = 1, \dots, B$, the function:

1. Extracts the bootstrap sample data .use.
2. Computes centred marker values at the subject and observation level.
3. Estimates index parameters by minimising `index_optim` using `optim`.
4. Computes the bootstrap hazard estimate via `Boot.hqm`.

The outputs are matrices collecting the hazard estimates and estimated index parameter vectors across bootstrap replicates.

Value

A matrix of dimension `n.est.points` \times `B` containing the bootstrap hazard estimates.

                             true.haz = true.hazard, v.param = c(0.07, 0.08), n.est.points = 100)

#return bootstrap hazard rate estimators in marix format:
res

```

bs.hqm

*Brier score for the High Quality Marker estimator***Description**

Calculates the Brier score for the HQM estimator.

Usage

```
bs.hqm(xin, est, landm, th, event_time_name, status_name)
```

Arguments

| | |
|-----------------|---|
| xin | A data frame containing event times and the patient status. |
| est | The HQM estimator values, typically the output of get_h_x . |
| landm | Landmark time. |
| th | Time horizon. |
| event_time_name | The column name of the event times in the data frame xin. |
| status_name | The column name of the status variable in the data frame xin. |

Details

The function [bs.hqm](#) implements the Brier score calculation for the HQM estimator estimator.

Value

Scalar: the Brier score of the HQM estimator.

BwB.HRandIndex.param *Bootstrap Estimation of Hazard Function and Index Parameters*

Description

Performs bootstrap estimation of hazard rates and their standard deviation at each grid point (double bootstrap) together with the corresponding index parameters for a given set of bootstrap samples. The output of the function is used as input in `StudentizedBwB.Index.CIs`.

Usage

```
BwB.HRandIndex.param(B, B1, Boot.samples, marker_name1, marker_name2,
                     event_time_name, time_name, event_name, b, t, true.haz,
                     v.param, hqm.est, id, xin)
```

Arguments

| | |
|-----------------|--|
| B | Integer. Number of bootstrap samples. |
| B1 | Integer. Number of bootstrap re-samples. |
| Boot.samples | A list of bootstrap datasets. Each element corresponds to one replicate. |
| marker_name1 | Character string. Name of the first longitudinal marker. |
| marker_name2 | Character string. Name of the second longitudinal marker. |
| event_time_name | Name of the event time variable in the data. |
| time_name | Name of the time variable for the longitudinal marker measurements. |
| event_name | Name of the event indicator variable. |
| b | Numeric. Bandwidth parameter used in hazard estimation. |
| t | Numeric. Evaluation point for the conditional hazard. |
| true.haz | Numeric vector. The true or reference hazard used in the optimisation criterion. |
| v.param | Numeric vector. Starting values of the indexing parameters for the optimisation of the index coefficients. |
| hqm.est | HQM estimator on the original sample. |
| id | label of id variable of dataset. |
| xin | original sample. |

Details

For each bootstrap iteration $k = 1, \dots, B$, the function:

1. Extracts the bootstrap sample data.use.
2. Computes centred marker values at the subject and observation level.
3. Estimates index parameters by minimising `index_optim` using `optim`.
4. Computes the bootstrap hazard estimate via `Boot.hqm`.

The outputs are matrices collecting the hazard estimates and estimated index parameter vectors across bootstrap replicates.

Value

A list of matrices of dimension $n.est.points \times B$ containing the bootstrap hazard estimates, the logarithm of the hazard rate estimates and two vectors of the estimate's standard deviations at each grid point.

# See the example for function: StudentizedBwB.Index
```

| | |
|--------------------------|---|
| <code>b_selection</code> | <i>Cross validation bandwidth selection</i> |
|--------------------------|---|

Description

Implements the bandwidth selection for the future conditional hazard rate $\hat{h}_x(t)$ based on K-fold cross validation.

Usage

```
b_selection(data, marker_name, event_time_name = 'years',
            time_name = 'year', event_name = 'status2', I, b_list)
```

Arguments

| | |
|------------------------------|---|
| <code>data</code> | A data frame of time dependent data points. Missing values are allowed. |
| <code>marker_name</code> | The column name of the marker values in the data frame data . |
| <code>event_time_name</code> | The column name of the event times in the data frame data . |
| <code>time_name</code> | The column name of the times the marker values were observed in the data frame data . |
| <code>event_name</code> | The column name of the events in the data frame data . |
| <code>I</code> | Number of observations leave out for a K cross validation. |
| <code>b_list</code> | Vector of bandwidths that need to be tested. |

Details

The function `b_selection` implements the cross validation bandwidth selection for the future conditional hazard rate $\hat{h}_x(t)$ given by

$$b_{CV} = \operatorname{argmin}_b \sum_{i=1}^N \int_0^T \int_s^T Z_i(t) Z_i(s) (\hat{h}_{X_i(s)}(t-s) - h_{X_i(s)}(t-s))^2 dt ds,$$

where $\hat{h}_x(t)$ is a smoothed kernel density estimator of $h_x(t)$ and Z_i the exposure process of individual i . Note that $\hat{h}_x(t)$ is dependent on b .

Value

A list with the tested bandwidths and its cross validation scores.

Examples

```
I = 26
# For Albumin marker:
b_list = seq(0.9, 1.7, 0.1)

b_scores_alb = b_selection(pbc2, 'albumin', 'years', 'year', 'status2', I, b_list)
b_scores_alb[[2]][which.min(b_scores_alb[[1]])]

# For Bilirubin marker:
b_list = seq(3, 4, 0.1)
b_scores_bil = b_selection(pbc2, 'serBilir', 'years', 'year', 'status2', I, b_list)
b_scores_bil[[2]][which.min(b_scores_bil[[1]])]
b_scores_bil
```

b_selection_index_optim

Cross validation index parameter selection

Description

Implements the index parameter selection for two markers based on K-fold cross validation.

Usage

```
b_selection_index_optim(in.par, data, marker_name1, marker_name2,
  event_time_name = 'years', time_name = 'year', event_name = 'status2', I, b)
```

Arguments

| | |
|------------------------------|--|
| <code>in.par</code> | Vector of candidate values for the index parameters. |
| <code>data</code> | A data frame of time dependent data points. Missing values are allowed. |
| <code>marker_name1</code> | The column name of the first marker values in the data frame <code>data</code> . |
| <code>marker_name2</code> | The column name of the second marker values in the data frame <code>data</code> . |
| <code>event_time_name</code> | The column name of the event times in the data frame <code>data</code> . |
| <code>time_name</code> | The column name of the times the marker values were observed in the data frame <code>data</code> . |
| <code>event_name</code> | The column name of the events in the data frame <code>data</code> . |
| <code>I</code> | Number of observations leave out for a K cross validation. |
| <code>b</code> | scalar bandwidth for the HQM estimator. |

Details

The function `b_selection_index_optim` implements the cross validation index parameter selection for the indexing of two markers and given by

$$\hat{\theta} = \underset{\theta_1, \theta_2}{\operatorname{argmin}} \sum_{i=1}^N \int_0^T \int_s^T Z_i(t) Z_i(s) (\hat{h}_{\theta_0^T X_i(s)}(t-s) - h_{\theta_0^T X_i(s)}(t-s))^2 dt ds,$$

where $\hat{h}_x(t)$ is the HQM estimator of $h_x(t)$, see Bagkavos et al. (2025), doi:10.1093/biomet/asaf008, and Z_i the exposure process of individual i . Note that $\hat{h}_x(t)$ is dependent on b .

Value

A list with the tested parameters and its cross validation scores.

}

```

b_selection_prep_g *Preparations for bandwidth selection*

Description

Calculates an intermediate part for the K-fold cross validation.

Usage

```
b_selection_prep_g(h_mat, int_X, size_X_grid, n, Yi)
```

Arguments

| | |
|-------------|--|
| h_mat | A matrix of the estimator for the future conditional hazard rate for all values x and t. |
| int_X | Vector of the position of the observed marker values in the grid for marker values. |
| size_X_grid | Numeric value indicating the number of grid points for marker values. |
| n | Number of individuals. |
| Yi | A matrix made by make_Yi indicating the exposure. |

Details

The function `b_selection_prep_g` calculates a key component for the bandwidth selection

$$\hat{g}_i^{-I_j}(t) = \int_0^t Z_i(s) \hat{h}_{X_i(s)}^{-I_j}(t-s) ds,$$

where \hat{h}^{-I_j} is estimated without information from all counting processes i with $i \in I_j$ and Z is the exposure.

Value

A matrix with $\hat{g}_i^{-I_j}(t)$ for all individuals i and time grid points t .

```

| | |
|----------------|---|
| Compute.iid.KM | <i>Compute.iid.KM function implementation</i> |
|----------------|---|

Description

Calculates the AUC for the HQM estimator.

Usage

```
Compute.iid.KM(times,status)
```

Arguments

| | |
|--------|--|
| times | The vector of (censored) event-times. |
| status | The vector of event indicators at the corresponding value of the vector T. Censored observations must be denoted by the value 0. |

Details

test

Value

A vector of two values: the landmark time of the calculation and the AUC value.

See Also

[bs.hqm](#)

| | |
|---------------------------|---|
| compute_iid_decomposition | <i>IID decomposition for time-dependent AUC with IPCW</i> |
|---------------------------|---|

Description

Internal function implementing the influence function (iid) decomposition of the time-dependent Area Under the Curve (AUC) in the presence of right-censoring, using inverse probability of censoring weighting (IPCW).

This function reproduces the internal behavior of the corresponding routines from the `timeROC` package. It supports both standard survival settings and competing risks settings through automatic dispatch.

Usage

```
compute_iid_decomposition(t, n, cause, F01t, St,
                          weights, T, delta, marker, MatInt0TcidhatMcksurEff)
```

Arguments

| | |
|-------------------------|--|
| t | Numeric scalar. Time point at which the AUC is evaluated. |
| n | Integer. Sample size. |
| cause | Integer or numeric. Event type of interest. |
| F01t | Numeric. Estimated cumulative incidence function at time t for the event of interest. |
| St | Numeric. Estimated survival probability at time t. |
| weights | List. IPCW weights object returned by pec::ipcw. Must contain components IPCW.subjectTimes, IPCW.times, and times. |
| T | Numeric vector. Observed event or censoring times. |
| delta | Integer or numeric vector. Event indicator: 0 for censoring, cause for the event of interest, and other values for competing events. |
| marker | Numeric vector. Prognostic marker or risk score. |
| MatInt0TcidhatMCKsurEff | Numeric matrix. Influence function representation of the censoring distribution, typically obtained from Compute.iid.KM(). |

Details

The function computes the iid (influence function) representation of the time-dependent AUC estimator based on IPCW methodology.

Two cases are handled internally:

- **Survival setting:** only one event type is present (no competing risks).
- **Competing risks setting:** multiple event types are present, and the AUC is defined using different control definitions.

The implementation relies on pairwise comparisons between cases and controls, weighted by inverse probability of censoring weights. The iid representation is derived from a U-statistic formulation and incorporates the influence of the censoring distribution via martingale-based corrections.

The computational complexity is quadratic in the sample size.

Value

A list with the following components:

| | |
|----------------------------|---|
| iid_representation_AUC | Numeric vector of length n. Influence function values for the AUC estimator. |
| iid_representation_AUCstar | Numeric vector of length n. Alternative influence function corresponding to an alternative control definition (mainly relevant in competing risks). |
| seAUC | Numeric scalar. Estimated standard error of the AUC. |
| seAUCstar | Numeric scalar. Estimated standard error corresponding to AUCstar. |
| computation_times | Placeholder (numeric or NA). Included for compatibility with timeROC. |

Note

This is an internal utility function and is not intended for direct use by end users. It is provided for reproducibility and to avoid dependency on archived packages.

Author(s)

Adapted from the `timeROC` package.

Conf_bands

Confidence bands

Description

Implements the uniform and pointwise confidence bands for the future conditional hazard rate based on the last observed marker measure.

Usage

```
Conf_bands(data, marker_name, event_time_name = 'years',
           time_name = 'year', event_name = 'status2', x, b)
```

Arguments

| | |
|------------------------------|--|
| <code>data</code> | A data frame of time dependent data points. Missing values are allowed. |
| <code>marker_name</code> | The column name of the marker values in the data frame <code>data</code> . |
| <code>event_time_name</code> | The column name of the event times in the data frame <code>data</code> . |
| <code>time_name</code> | The column name of the times the marker values were observed in the data frame <code>data</code> . |
| <code>event_name</code> | The column name of the events in the data frame <code>data</code> . |
| <code>x</code> | Numeric value of the last observed marker value. |
| <code>b</code> | Bandwidth. |

Details

The function `Conf_bands` implements the pointwise and uniform confidence bands for the estimator of the future conditional hazard rate $\hat{h}_x(t)$. The confidence bands are based on a wild bootstrap approach $h^*_{x^*,B}(t)$.

Pointwise: For a given $t \in (0, T)$ generate $h^*_{x^*,B}(1)(t), \dots, h^*_{x^*,B}(N)(t)$ for $N = 1000$ and order it $h^*_{x^*,B}(1)(t) \leq \dots \leq h^*_{x^*,B}(N)(t)$. Then

$$\hat{I}_{n,N}^1 = \left[\hat{h}_{x^*}(t) - \hat{\sigma}_{G_{x^*}}(t) \frac{h^*_{x^*,B}^{[N(1-\frac{\alpha}{2})]}(t)}{\sqrt{n}}, \hat{h}_{x^*}(t) + \hat{\sigma}_{G_{x^*}}(t) \frac{h^*_{x^*,B}^{[N\frac{\alpha}{2}]}(t)}{\sqrt{n}} \right]$$

is a $1 - \alpha$ pointwise confidence band for $h_{x^*}(t)$, where $\hat{\sigma}_{G_{x^*}}(t)$ is a bootstrap estimate of the variance. For more details on the wild bootstrap approach, please see `prep_boot` and `g_xt`.

Uniform: Generate $\bar{h}^{(1)}_{x^*,B}(t), \dots, \bar{h}^{(N)}_{x^*,B}(t)$ for $N = 1000$ for all $t \in [\delta_T, T - \delta_T]$ and define $W^{(i)} = \sup_{t \in [0, T]} |\bar{h}^{(i)}_{x^*,B}(t)|$ for $i = 1, \dots, N$. Order $W^{[1]} \leq \dots \leq W^{[N]}$. Then

$$\hat{I}_{n,N}^2 = \left[\hat{h}_{x^*}(t) \pm \hat{\sigma}_{G_{x^*}}(t) \frac{W^{[N(1-\alpha)]}}{\sqrt{n}} \right]$$

is a $1 - \alpha$ uniform confidence band for $h_{x^*}(t)$.

Value

A list with pointwise, uniform confidence bands and the estimator $\hat{h}_x(t)$ for all possible time points t .

See Also

`g_xt`, `prep_boot`

Examples

```
b = 10
x = 3
size_s_grid <- 100
s = pbc2$year
br_s = seq(0, max(s), max(s)/(size_s_grid-1))

c_bands = Conf_bands(pbc2, 'serBilir', event_time_name = 'years',
                    time_name = 'year', event_name = 'status2', x, b)

J = 80
plot(br_s[1:J], c_bands$h_hat[1:J], type = "l", ylim = c(0,1), ylab = 'Hazard', xlab = 'Years')

lines(br_s[1:J], c_bands$I_p_up[1:J], col = "red")
lines(br_s[1:J], c_bands$I_p_do[1:J], col = "red")

```

| | |
|---------------|--|
| dataset_split | <i>Split dataset for K-fold cross validation</i> |
|---------------|--|

Description

Creates multiple splits of a dataset which is then used in the bandwidth selection with K-fold cross validation.

Usage

```
dataset_split(I, data)
```

Arguments

| | |
|------|---|
| data | A data frame of time dependent data points. Missing values are allowed. |
| I | The number of individuals that should be left out. Optimally, $K = n/I$ should be an integer, where n is the number of individuals. |

Details

The function `dataset_split` takes a data frame and transforms it into $K = n/I$ data frames with I individuals missing from each data frame. Let I_j be sets of indices with $\cup_{j=1}^K I_j = \{1, \dots, n\}$, $I_k \cap I_j = \emptyset$ and $|I_j| = |I_k| = I$ for all $j, k \in \{1, \dots, K\}$. Then data frames with $\{1, \dots, n\}/I_j$ individuals are created.

Value

A list of data frames with `I` individuals missing in the above way.

```
splitted_dataset = dataset_split(26, pbc2)
```

| | |
|------|---|
| di j | <i>D matrix entries, used for the implementation of the local linear kernel</i> |
|------|---|

Description

Calculates the entries of the D matrix in the definition of the local linear kernel

Usage

di j(b, x, y, K)

Arguments

| | |
|---|---|
| x | A vector of design points where the kernel will be evaluated. |
| y | A vector of sample data points. |
| b | The bandwidth to use (a scalar). |
| K | The kernel function to use. |

Details

Implements the calculation of all $d \times d$ entries of matrix D , which is part of the definition of the local linear kernel. The actual calculation is performed by

$$d_{jk} = \sum_{i=1}^n \int_0^T K_b(x - X_i(s)) \{x - X_{ij}(s)\} \{x - X_{ik}(s)\} Z_i(s) ds,$$

Value

scalar value, the result of d_{jk} .

| | |
|------|----------------------------|
| Epan | <i>Epanechnikov kernel</i> |
|------|----------------------------|

Description

Implements the Epanechnikov kernel function

Usage

Epan(x)

Arguments

| | |
|---|---|
| x | A vector of design points where the kernel will be evaluated. |
|---|---|

Details

Implements the Epanechnikov kernel function

$$K(x) = \frac{3}{4}(1 - x^2) * (|x| < 1),$$

Value

Scalar, the value of the Epanechnikov kernel at x .

| | |
|-----------|--------------------------------|
| get_alpha | <i>Marker-only hazard rate</i> |
|-----------|--------------------------------|

Description

Calculates the marker-only hazard rate for time dependent data.

Usage

```
get_alpha(N, Y, b, br_X, K=Epan )
```

Arguments

| | |
|------|---|
| N | A matrix made by make_N indicating the occurrences of events. |
| Y | A matrix made by make_Y indicating the exposure. |
| b | Bandwidth. |
| br_X | Vector of grid points for the marker values X . |
| K | Used kernel function. |

Details

The function [get_alpha](#) implements the marker-only hazard estimator

$$\hat{\alpha}_i(z) = \frac{\sum_{k \neq i} \int_0^T K_{b_1}(z - X_k(s)) dN_k(s)}{\sum_{k \neq i} \int_0^T K_{b_1}(z - X_k(s)) Z_k(s) ds},$$

where X is the marker and Z is the exposure. The marker-only hazard is defined as the underlying hazard which is not dependent on time

$$\alpha(X(t), t) = \alpha(X(t)).$$

Value

A vector of marker-only values for br_X.

get_h_x

*Local constant future conditional hazard rate estimator***Description**

Calculates the (indexed) local constant future hazard rate function, conditional on a marker value x , across across a set of time values t .

Usage

```
get_h_x(data, marker_name, br_s, event_time_name, time_name, event_name, x, b)
```

Arguments

| | |
|-----------------|---|
| data | A data frame of time dependent data points. Missing values are allowed. |
| marker_name | The column name of the marker values in the data frame data . |
| br_s | User defined grid mesh on time_name variable |
| event_time_name | The column name of the event times in the data frame data . |
| time_name | The column name of the times the marker values were observed in the data frame data . |
| event_name | The column name of the events in the data frame data . |
| x | Numeric value of the last observed marker value. |
| b | Bandwidth parameter. |

Details

The function `get_h_x` implements the indexed local linear future conditional hazard estimator

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(\hat{\theta}^T X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds},$$

across a grid of possible time values t , where, for a positive integer p , $\hat{\theta}^T = (\hat{\theta}_1, \dots, \hat{\theta}_p)$ is the vector of the estimated indexing parameters, $X_i = (X_{1,i}, \dots, X_{p,i})$ is a vector of markers for indexing, Z_i is the exposure and $\alpha(z)$ is the marker-only hazard, see `get_alpha` for more details and $K_b = b^{-1}K(\cdot/b)$ is an ordinary kernel function, e.g. the Epanechnikov kernel. For $p = 1$ and $\hat{\theta} = 1$ the above estimator becomes the HQM hazard rate estimator conditional on one covariate,

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds},$$

defined in equation (2) of Bagkavos et al. (2025), [doi:10.1093/biomet/asaf008](https://doi.org/10.1093/biomet/asaf008).

Value

A vector of $\hat{h}_x(t)$ for a grid of possible time values t .

get_h_xll

Local linear future conditional hazard rate estimator

Description

Calculates the (indexed) local linear future hazard rate function, conditional on a marker value x , across a set of time values t .

Usage

```
get_h_xll(data, marker_name, br_s, event_time_name, time_name, event_name, x, b)
```

Arguments

| | |
|------------------------------|--|
| <code>data</code> | A data frame of time dependent data points. Missing values are allowed. |
| <code>marker_name</code> | The column name of the marker values in the data frame <code>data</code> . |
| <code>br_s</code> | User defined grid mesh on <code>time_name</code> variable |
| <code>event_time_name</code> | The column name of the event times in the data frame <code>data</code> . |
| <code>time_name</code> | The column name of the times the marker values were observed in the data frame <code>data</code> . |

| | |
|------------|---|
| event_name | The column name of the events in the data frame <code>data</code> . |
| x | Numeric value of the last observed marker value. |
| b | Bandwidth parameter. |

Details

The function `get_h_xll` uses a local linear kernel to implement the indexed local linear future conditional hazard estimator

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(\hat{\theta}^T X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds},$$

across a grid of possible time values t , where, for a positive integer p , $\hat{\theta}^T = (\hat{\theta}_1, \dots, \hat{\theta}_p)$ is the vector of the estimated indexing parameters, $X_i = (X_{1,i}, \dots, X_{p,i})$ is a vector of markers for indexing, Z_i is the exposure and $\alpha(z)$ is the marker-only hazard, see `get_alpha` for more details. For $p = 1$ and $\hat{\theta} = 1$ the above estimator becomes the HQM hazard rate estimator conditional on one covariate,

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds},$$

defined in equation (2) of Bagkavos et al. (2025) doi:10.1093/biomet/asaf008. In the place of $K_b(\cdot)$, `get_h_xll` uses the kernel

$$K_{x,b}(u) = \frac{K_b(u) - K_b(u)u^T D^{-1}c_1}{c_0 - c_1^T D^{-1}c_1},$$

where $K_b(\cdot) = b^{-1}K(\cdot/b)$ with K being an ordinary kernel, e.g. the Epanechnikov kernel, $c_1 = (c_{11}, \dots, c_{1d})^T$, $D = (d_{ij})_{(d+1) \times (d+1)}$ with

$$c_0 = \sum_{i=1}^n \int_0^T K_b(x - \hat{\theta}^T X_i(s)) Z_i(s) ds,$$

$$c_{ij} = \sum_{i=1}^n \int_0^T K_b(x - \hat{\theta}^T X_i(s)) \{x - \hat{\theta}^T X_{ij}(s)\} Z_i(s) ds,$$

$$d_{jkl} = \sum_{i=1}^n \int_0^T K_b(x - \hat{\theta}^T X_i(s)) \{x - \hat{\theta}^T X_{ij}(s)\} \{x - \hat{\theta}^T X_{ik}(s)\} Z_i(s) ds,$$

see also Nielsen (1998), doi:10.1080/03461238.1998.10413997.

Value

A vector of $\hat{h}_x(t)$ for a grid of possible time values t .

```

g_xt

Computation of a key component for wild bootstrap

Description

Implements a key part for the wild bootstrap of the hqm estimator.

Usage

```
g_xt(br_X, br_s, size_s_grid, int_X, x, t, b, Yi, Y, n)
```

Arguments

| | |
|-------------|---|
| br_X | Marker value grid points that will be used in the evaluation. |
| br_s | Time value grid points that will be used in the evaluation. |
| size_s_grid | Size of the time grid. |
| int_X | Position of the linear interpolated marker values on the marker grid. |
| x | Numeric value of the last observed marker value. |
| t | Numeric value of the time the function should be evaluated. |
| b | Bandwidth. |
| Yi | A matrix made by <code>make_Yi</code> indicating the exposure. |
| Y | A matrix made by <code>make_Y</code> indicating the exposure. |
| n | Number of individuals. |

Details

The function implements

$$\hat{g}_{t,x}(z) = \frac{1}{n} \sum_{j=1}^n \int_0^{T-t} \hat{E}(X_j(t+s))^{-1} K_b(z, X_j(t+s)) Z_j(t+s) Z_j(s) K_b(x, X_j(s)) ds,$$

for every value z on the marker grid, where $\hat{E}(x) = \frac{1}{n} \sum_{j=1}^n \int_0^T K_b(x, X_j(s)) Z_j(s) ds$, Z the exposure and X the marker.

Value

A vector of $\hat{g}_{t,x}(z)$ for all values z on the marker grid.

Examples

```

pbc2_id = to_id(pbc2)
size_s_grid <- size_X_grid <- 100
n = max(as.numeric(pbc2$id))
X = pbc2$serBilir
s = pbc2$year
br_s = seq(0, max(s), max(s)/(size_s_grid-1))

g_xt(br_X, br_s, size_s_grid, int_X, x, t, b, Yi, Y, n)

```

h_xt *Local constant future conditional hazard rate estimation at a single time point*

Description

Calculates the (indexed) future conditional hazard rate for a marker value x and a time value t .

Usage

```
h_xt(br_X, br_s, int_X, size_s_grid, alpha, x,t, b, Yi,n)
```

Arguments

| | |
|-------------|---|
| br_X | Vector of grid points for the marker values X . |
| br_s | Vector of grid points for the time values s . |
| int_X | Position of the linear interpolated marker values on the marker grid. |
| size_s_grid | Size of the time grid. |
| alpha | Marker-hazard obtained from get_alpha . |
| x | Numeric value of the last observed marker value. |
| t | Numeric time value. |
| b | Bandwidth. |
| Yi | A matrix made by make_Yi indicating the exposure. |
| n | Number of individuals. |

Details

Function [h_xt](#) implements the future conditional hazard estimator

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(\hat{\theta}^T X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds},$$

where, for a positive integer p , $\hat{\theta}^T = (\hat{\theta}_1, \dots, \hat{\theta}_p)$ is the vector of the estimated indexing parameters, $X_i = (X_{1,i}, \dots, X_{i,p})$ is a vector of markers for indexing, Z_i is the exposure and $\alpha(z)$ is the marker-only hazard, see [get_alpha](#) for more details and $K_b = b^{-1}K(\cdot/b)$ is an ordinary kernel function, e.g. the Epanechnikov kernel. For $p = 1$ and $\hat{\theta} = 1$ the above estimator becomes the HQM hazard rate estimator conditional on one covariate,

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds},$$

defined in equation (2) of Bagkavos et al. (2025) [doi:10.1093/biomet/asaf008](https://doi.org/10.1093/biomet/asaf008).

The future conditional hazard is defined as

$$h_{x,T}(t) = P(T_i \in (t+T, t+T+dt) | \theta_0^T X_i(T) = x, T_i > t+T),$$

where T_i is the survival time and X_i the marker of individual i observed in the time frame $[0, T]$.

Value

A single numeric value of $\hat{h}_x(t)$.

Details

Function [h_xtll](#) implements the future local linear conditional hazard estimator

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(\hat{\theta}^T X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - \hat{\theta}^T X_i(s)) ds},$$

for every x on the marker grid, where, for a positive integer p , $\hat{\theta}^T = (\hat{\theta}_1, \dots, \hat{\theta}_p)$ is the vector of the estimated indexing parameters, $X_i = (X_{1,i}, \dots, X_{i,p})$ is a vector of markers for indexing, Z_i is the exposure and $\alpha(z)$ is the marker-only hazard, see [get_alpha](#) for more details. For $p = 1$ and $\hat{\theta} = 1$ the above estimator becomes the HQM hazard rate estimator conditional on a single covariate,

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds},$$

defined in equation (2) of Bagkavos et al. (2025) doi:10.1093/biomet/asaf008. In the place of $K_b()$, `h_xtll` uses the kernel

$$K_{x,b}(u) = \frac{K_b(u) - K_b(u)u^T D^{-1}c_1}{c_0 - c_1^T D^{-1}c_1},$$

where $K_b(\cdot) = b^{-1}K(\cdot/b)$ with K being an ordinary kernel, e.g. the Epanechnikov kernel, $c_1 = (c_{11}, \dots, c_{1d})^T$, $D = (d_{ij})_{(d+1) \times (d+1)}$ with

$$c_0 = \sum_{i=1}^n \int_0^T K_b(x - \hat{\theta}^T X_i(s)) Z_i(s) ds,$$

$$c_{ij} = \sum_{i=1}^n \int_0^T K_b(x - \hat{\theta}^T X_i(s)) \{x - \hat{\theta}^T X_{ij}(s)\} Z_i(s) ds,$$

$$d_{jk} = \sum_{i=1}^n \int_0^T K_b(x - \hat{\theta}^T X_i(s)) \{x - \hat{\theta}^T X_{ij}(s)\} \{x - \hat{\theta}^T X_{ik}(s)\} Z_i(s) ds,$$

see also Nielsen (1998) doi:10.1080/03461238.1998.10413997.

The future conditional hazard is defined as

$$h_{x,T}(t) = P(T_i \in (t+T, t+T+dt) | \theta_0^T X_i(T) = x, T_i > t+T),$$

where T_i is the survival time and X_i the marker of individual i observed in the time frame $[0, T]$.

Value

A single numeric value of $\hat{h}_x(t)$.

| | |
|-------------|--|
| index_optim | <i>Indexing parameter objective function</i> |
|-------------|--|

Description

Objective used for optimizing indexing parameters via `optim`.

Usage

```
index_optim(in.par, data, data.id, br_s, X1, XX1, event_time_name = 'years',
            time_name = 'year', event_name = 'status2', b, t, true.haz)
```

Arguments

| | |
|------------------------------|--|
| <code>in.par</code> | Numeric vector length 2. |
| <code>data</code> | Data frame. |
| <code>data.id</code> | Id-level data frame. |
| <code>br_s</code> | user-supplied grid points ranging from the minimum to the maximum of the <code>time_name</code> argument |
| <code>X1</code> | List of vectors for indexing: each vector corresponds to a biomarker and contains one summary measurement per individual. |
| <code>XX1</code> | List of vectors for indexing: each vector corresponds to a single biomarker and contains its longitudinal measurements across all individuals/time points. |
| <code>event_time_name</code> | Name of event time column. |
| <code>time_name</code> | Name of observation time column. |
| <code>event_name</code> | Name of event indicator column. |
| <code>b</code> | Bandwidth. |
| <code>t</code> | Evaluation point or grid. |
| <code>true.haz</code> | Numeric vector of true hazard values for CV. |

Value

Scalar cross-validation score.

Examples

```

marker_name1 <- 'albumin'
marker_name2 <- 'serBilir'
event_time_name <- 'years'
time_name <- 'year'
event_name <- 'status2'
id<-'id'

par.x1 <- 0.0702 #0.149
par.x2 <- 0.0856 #0.10
t.x1 = 0 # refers to zero mean variables - slightly high
t.x2 = 1.9 # refers to zero mean variable - high
b = 0.42
t = par.x1 * t.x1 + par.x2 *t.x2

# first simulate true HR function:
xin <- pbc2[,c(id, marker_name1, marker_name2, event_time_name, time_name, event_name)]
ls<-50 # 50 grid points to evaluate the estimates
s.out<- xin[, 'year']
s.out.use <- seq(0, max(s.out), max(s.out)/( ls-1))

n <- length(xin$id)
nn<-max( as.double(xin[, 'id']) )
##### Create bootstrap samples by group #####
set.seed(1)
B<- 10 # 400 #50
Boot.samples<-list()
for(j in 1:B)
{
  i.use<-c()
  id.use<-c()
  index.nn <- sample (nn, replace = TRUE)
  for(l in 1:nn)
  {
    i.use2<-which(xin[,id]==index.nn[l])
    i.use<-c(i.use, i.use2)
    id.use2<-rep(index.nn[l], times=length(i.use2))
    id.use<-c(id.use, id.use2)
  }
  xin.i<-xin[i.use,]
  xin.i<-xin[i.use,]
  Boot.samples[[j]]<- xin.i[order(xin.i$id),] #xin[i.use,]
}
true.hazard<- Sim.True.Hazard(Boot.samples, id='id', size_s_grid=ls,
  marker_name1=marker_name1, marker_name2= marker_name2,
  event_time_name = event_time_name,
  time_name = time_name, event_name = event_name,
  in.par = c(par.x1, par.x2), b)
#####

```

```

# Then run the optimization for the indexing parameters:

data.use<-Boot.samples[[1]]
data.use.id<-to_id(data.use)
data.use.id<-data.use.id[complete.cases(data.use.id), ]
X1t=data.use[,marker_name1] -mean(data.use[, marker_name1])
XX1t=data.use.id[,marker_name1] -mean(data.use.id[, marker_name1])
X2t=data.use[,marker_name2] -mean(data.use[, marker_name2])
XX2t=data.use.id[,marker_name2] -mean(data.use.id[, marker_name2])

X1=list(X1t, X2t)
XX1=list(XX1t, XX2t)

s.out<- data.use[, time_name]

           time_name = time_name, event_name = event_name, b=b, t=t,
           true.haz=true.hazard, method="Nelder-Mead")

```

Kernels

Classical (unmodified) kernel and related functionals

Description

Implements the classical kernel function and related functionals

Usage

```

K_b(b,x,y, K)
xK_b(b,x,y, K)
K_b_mat(b,x,y, K)

```

Arguments

| | |
|---|---|
| x | A vector of design points where the kernel will be evaluated. |
| y | A vector of sample data points. |
| b | The bandwidth to use (a scalar). |
| K | The kernel function to use. |

Details

The function `K_b` implements the classical kernel function calculation

$$h^{-1}K\left(\frac{x-y}{h}\right)$$

for scalars x and y while `xK_b` implements the functional

$$h^{-1}K\left(\frac{x-y}{h}\right)(x-y)$$

again for for scalars x and y . The function `K_b_mat` is the vectorized version of `K_b`. It uses as inputs the vectors (X_1, \dots, X_n) and (Y_1, \dots, Y_n) and returns a $n \times n$ matrix with entries

$$h^{-1}K\left(\frac{X_i - Y_j}{h}\right)$$

Value

Scalar values for `K_b` and `xK_b` and matrix outputs for `K_b_mat`.

| | |
|-----------------|-----------------------------|
| lin_interpolate | <i>Linear interpolation</i> |
|-----------------|-----------------------------|

Description

Implements a linear interpolation between observed marker values.

Usage

```
lin_interpolate(t, i, data_id, data_marker, data_time)
```

Arguments

| | |
|--------------------------|---|
| <code>t</code> | A vector of time values where the function should be evaluated. |
| <code>i</code> | A vector of ids of individuals for whom the marker values should be interpolated. |
| <code>data_id</code> | The vector of ids from a data frame of time dependent variables. |
| <code>data_marker</code> | The vector of marker values from a data frame of time dependent variables. |
| <code>data_time</code> | The vector of time values from a data frame of time dependent variables. |

Details

Given time points t_1, \dots, t_K and marker values m_1, \dots, m_J at different time points t_1^m, \dots, t_J^m , the function calculates a linear interpolation f with $f(t_i^m) = m_i$ at the time points t_1, \dots, t_K for all indicated individuals. Returned are then $(f(t_1), \dots, f(t_K))$. Note that the first value is always observed at time point 0 and the function f is extrapolated constantly after the last observed marker value.

Value

A matrix with columns $(f(t_1), \dots, f(t_K))$ as described above for every individual in the vector `i`.

Examples

```

size_s_grid <- 100
X = pbc2$serBilir
s = pbc2$year
br_s = seq(0, max(s), max(s)/( size_s_grid-1))
pbc2_id = to_id(pbc2)

X_lin = lin_interpolate(br_s, pbc2_id$id, pbc2$id, X, s)

```

llk_b

*Local linear kernel***Description**

Implements the local linear kernel function.

Usage

```
llk_b(b,x,y, K)
```

Arguments

x A vector of design points where the kernel will be evaluated.
y A vector of sample data points.
b The bandwidth to use (a scalar).
K The kernel function to use.

Details

Implements the local linear kernel

$$K_{x,b}(u) = \frac{K_b(u) - K_b(u)u^T D^{-1}c_1}{c_0 - c_1^T D^{-1}c_1},$$

where $c_1 = (c_{11}, \dots, c_{1d})^T$, $D = (d_{ij})_{(d+1) \times (d+1)}$ with

$$c_0 = \sum_{i=1}^n \int_0^T K_b(x - X_i(s))Z_i(s)ds,$$

$$c_{ij} = \sum_{i=1}^n \int_0^T K_b(x - X_i(s))\{x - X_{ij}(s)\}Z_i(s)ds,$$

$$d_{jk} = \sum_{i=1}^n \int_0^T K_b(x - X_i(s))\{x - X_{ij}(s)\}\{x - X_{ik}(s)\}Z_i(s)ds,$$

see also Nielsen (1998), doi:[10.1080/03461238.1998.10413997](https://doi.org/10.1080/03461238.1998.10413997).

Value

Matrix output with entries the values of the kernel function at each point.

References

Nielsen (1998), Marker dependent kernel hazard estimation from local linear estimation, Scandinavian Actuarial Journal, pp. 113-124. [doi:10.1080/03461238.1998.10413997](https://doi.org/10.1080/03461238.1998.10413997)

llweights

Local linear weight functions

Description

Implements the weights to be used in the local linear HQM estimator.

Usage

```
sn.0(xin, xout, h, kfun)
sn.1(xin, xout, h, kfun)
sn.2(xin, xout, h, kfun)
```

Arguments

| | |
|------|--|
| xin | Sample values. |
| xout | Grid points where the estimator will be evaluated. |
| h | Bandwidth parameter. |
| kfun | Kernel function. |

Details

The function implements the local linear weights in the definition of the estimator $\hat{h}_x(t)$, see also [h_xt](#)

Value

A vector of $s_n(x)$ for all values x on the marker grid.

 make_N, make_Ni, make_Y, make_Yi

Occurance and Exposure on grids

Description

Auxiliary functions that help automate the process of calculating integrals with occurrences or exposure processes.

Usage

```
make_N(data, data.id, breaks_X, breaks_s, ss, XX, delta)
make_Ni(breaks_s, size_s_grid, ss, delta, n)
make_Y(data, data.id, X_lin, breaks_X, breaks_s,
        size_s_grid, size_X_grid, int_s, int_X, event_time = 'years', n)
make_Yi(data, data.id, X_lin, breaks_X, breaks_s,
         size_s_grid, size_X_grid, int_s, int_X, event_time = 'years', n)
```

Arguments

| | |
|-------------|--|
| data | A data frame of time dependent data points. Missing values are allowed. |
| data.id | An id data frame obtained from to_id . |
| breaks_X | Marker value grid points where the function will be evaluated. |
| breaks_s | Time value grid points where the function will be evaluated. |
| ss | Vector with event times. |
| XX | Vector of last observed marker values. |
| delta | 0-1 vector of whether events happened. |
| size_s_grid | Size of the time grid. |
| size_X_grid | Size of the marker grid. |
| n | Number of individuals. |
| X_lin | Linear interpolation of observed marker values evaluated on the marker grid. |
| int_s | Position of the observed time values on the time grid. |
| int_X | Position of the linear interpolated marker values on the marker grid. |
| event_time | String of the column name with the event times. |

Details

Implements matrices for the computation of integrals with occurrences and exposures of the form

$$\int f(s)Z(s)Z(s+t)ds, \int f(s)Z(s)ds, \int f(s)dN(s).$$

where N is a 0-1 counting process, Z the exposure and f an arbitrary function.

Value

The functions `make_N` and `make_Y` return a matrix on the time grid and marker grid for occurrence and exposure, respectively, while `make_Ni` and `make_Yi` return a matrix on the time grid for every individual again for occurrence and exposure, respectively.

See Also

`h_xt`, `g_xt`, `get_alpha`

Examples

```

pbc2_id = to_id(pbc2)
size_s_grid <- size_X_grid <- 100
n = max(as.numeric(pbc2$id))
s = pbc2$year
X = pbc2$serBilir
XX = pbc2_id$serBilir
ss <- pbc2_id$years
delta <- pbc2_id$status2
br_s = seq(0, max(s), max(s)/( size_s_grid-1))
br_X = seq(min(X), max(X), (max(X)-min(X))/( size_X_grid-1))

X_lin = lin_interpolate(br_s, pbc2_id$id, pbc2$id, X, s)

int_X <- findInterval(X_lin, br_X)
int_s = rep(1:length(br_s), n)

N <- make_N(pbc2, pbc2_id, br_X, br_s, ss, XX, delta)
Y <- make_Y(pbc2, pbc2_id, X_lin, br_X, br_s,
           size_s_grid, size_X_grid, int_s, int_X, event_time = 'years', n)
Yi <- make_Yi(pbc2, pbc2_id, X_lin, br_X, br_s,
             size_s_grid, size_X_grid, int_s, int_X, event_time = 'years', n)
Ni <- make_Ni(br_s, size_s_grid, ss, delta, n)

```

make_sf

Survival function from a hazard

Description

Creates a survival function from a hazard rate which was calculated on a grid.

Usage

```
make_sf(step_size_s_grid, haz)
```

Arguments

- `step_size_s_grid` Numeric value indicating the distance between two grid continuous grid points.
- `haz` Vector of hazard values. Hazard rate must have been calculated on a time grid.

Details

The function `make_sf` calculates the survival function

$$S(t) = \exp\left(-\int_0^t h(t)dt\right),$$

where h is the hazard rate. Here, a discretisation via an equidistant grid $\{t_i\}$ on $[0, t]$ is used to calculate the integral and it is assumed that h has been calculated for exactly these time points t_i .

Value

A vector of values $S(t_i)$.

Examples

```
make_sf(0.1, rep(0.1,10))
```

pbc2

Mayo Clinic Primary Biliary Cirrhosis Data

Description

Followup of 312 randomised patients with primary biliary cirrhosis, a rare autoimmune liver disease, at Mayo Clinic.

Usage

```
pbc2
```

Format

A data frame with 1945 observations on the following 20 variables.

`id` patients identifier; in total there are 312 patients.

`years` number of years between registration and the earlier of death, transplantation, or study analysis time.

`status` a factor with levels alive, transplanted and dead.

`drug` a factor with levels placebo and D-penicil.

`age` at registration in years.

`sex` a factor with levels male and female.

year number of years between enrollment and this visit date, remaining values on the line of data refer to this visit.

ascites a factor with levels No and Yes.

hepatomegaly a factor with levels No and Yes.

spiders a factor with levels No and Yes.

edema a factor with levels No edema (i.e., no edema and no diuretic therapy for edema), edema no diuretics (i.e., edema present without diuretics, or edema resolved by diuretics), and edema despite diuretics (i.e., edema despite diuretic therapy).

serBilir serum bilirubin in mg/dl.

serChol serum cholesterol in mg/dl.

albumin albumin in gm/dl.

alkaline alkaline phosphatase in U/liter.

SGOT SGOT in U/ml.

platelets platelets per cubic ml / 1000.

prothrombin prothrombin time in seconds.

histologic histologic stage of disease.

status2 a numeric vector with the value 1 denoting if the patient was dead, and 0 if the patient was alive or transplanted.

|-----------------|--|
| Pivot.Index.CIs | <i>Compute Pivot Pointwise Confidence Intervals for the Indexed Hazard Rate Estimate</i> |
|-----------------|--|

Description

Computes bootstrap pivot and symmetric bootstrap-pivot confidence intervals for the hazard, log-hazard, and back-transformed (log-scale) hazard rate functions, using the indexed hazard estimator.

Usage

```
Pivot.Index.CIs(B, n.est.points, Mat.boot.haz.rate, time.grid, hqm.est, a.sig)
```

Arguments

| | |
|-------------------|---|
| B | Integer. Number of bootstrap replications |
| n.est.points | Integer. Number of estimation points at which the indexed hazard estimates and confidence intervals are evaluated. |
| Mat.boot.haz.rate | A matrix of bootstrap estimated hazard rates with dimensions n.est.points \times B, where each column corresponds to one bootstrap replicate. |
| time.grid | Numeric vector of length n.est.points: the grid points at which the indexed hazard estimates and confidence intervals are calculated. |
| hqm.est | Indexed hazard estimator, calculated at the grid points time.grid and using the original sample. |
| a.sig | The significance level (e.g., 0.05) which will be used in computing the confidence intervals. |

Details

This function computes several forms of pivot confidence intervals for indexed hazard rate estimates. Let $\hat{\sigma}$ be the sample standard deviation of the bootstrap estimators $\hat{h}_x^{(j)}(t)$, $j = 1, \dots, B$ and let $k_{\alpha/2}^p$, $k_{1-\alpha/2}^p$ and $\bar{k}_{1-\alpha}^p$ be the $\alpha/2$, $1 - \alpha/2$ and $1 - \alpha$ quantiles respectively of

$$\frac{\hat{h}_x^{(j)}(t) - \hat{h}_x(t)}{\hat{\sigma}}, j = 1, \dots, B.$$

Then, the pivot bootstrap confidence interval (CI) for $\hat{h}_x(t)$ is given by

$$\left(\hat{h}_x(t) - \hat{\sigma} k_{1-\alpha/2}^p, \hat{h}_x(t) - \hat{\sigma} k_{\alpha/2}^p \right).$$

The symmetric pivot bootstrap CI for $\hat{h}_x(t)$ is

$$\left(\hat{h}_x(t) - \hat{\sigma} \bar{k}_{1-\alpha}^p, \hat{h}_x(t) + \hat{\sigma} \bar{k}_{1-\alpha}^p \right).$$

For the confidence intervals for the logarithm of the hazard rate function, first let

$$L_x(t) = \log \{h_x(t)\}, \hat{L}_x(t) = \log \{ \hat{h}_x(t) \}, \hat{L}_x^{(j)}(t) = \log \{ \hat{h}_x^{(j)}(t) \},$$

and $k_{\alpha/2}^{L,p}$, $k_{1-\alpha/2}^{L,p}$ and $\bar{k}_{1-\alpha}^{L,p}$ be respectively the $\alpha/2$, $1 - \alpha/2$ and $1 - \alpha$ quantile of

$$\frac{|\hat{L}_x^{(j)}(t) - \hat{L}_x(t)|}{\hat{\sigma}}, j = 1, \dots, B.$$

For the log hazard function $L_x(t)$ a pivotal bootstrap confidence interval is

$$\left(\hat{L}_x(t) - \hat{\sigma} k_{1-\alpha/2}^{L,p}, \hat{L}_x(t) - \hat{\sigma} k_{\alpha/2}^{L,p} \right).$$

A symmetric pivotal bootstrap CI for the log hazard is

$$\left(\hat{L}_x(t) - \hat{\sigma} \bar{k}_{1-\alpha}^{L,p}, \hat{L}_x(t) + \hat{\sigma} \bar{k}_{1-\alpha}^{L,p} \right).$$

These last two confidence intervals can be transformed back to yield confidence intervals for the hazard rate function $h_x(t)$. These are:

$$\left(\hat{h}_x(t) e^{-\hat{\sigma} \bar{k}_{1-\alpha/2}^{L,p}}, \hat{h}_x(t) e^{-\hat{\sigma} \bar{k}_{\alpha/2}^{L,p}} \right),$$

and

$$\left(\hat{h}_x(t) e^{-\hat{\sigma} \bar{k}_{1-\alpha}^{L,p}}, \hat{h}_x(t) e^{\hat{\sigma} \bar{k}_{1-\alpha}^{L,p}} \right)$$

respectively.

Note: The bootstrap matrix `Mat.boot.haz.rate` is assumed to contain estimates produced using the same time grid as `time.grid` and the same estimator used to generate `hqm.est`.

Value

A data frame with the following columns:

| | |
|---------------------------------------|--|
| <code>time</code> | The evaluation grid points. |
| <code>est</code> | Indexed hazard rate estimator <code>hqm.est</code> . |
| <code>downci, upci</code> | Lower and upper endpoints of basic pivot CIs. |
| <code>docisym, upcisym</code> | Lower and upper endpoints of symmetric pivot CIs. |
| <code>logdoci, logupci</code> | Lower and upper endpoints of pivot CIs on the log-scale. |
| <code>logdocisym, logupcisym</code> | Symmetric pivot CIs on the log-scale. |
| <code>log.est</code> | The logarithm of the indexed hazard rate estimate, <code>log(hqm.est)</code> . |
| <code>tLogDoCI, tLogUpCI</code> | Transformed-log CIs based on $2 * \log(hqm.est) - \log$ -quantiles. |
| <code>tSymLogDoCI, tSymLogUpCI</code> | Symmetric transformed-log CIs. |

Precomputation for wild bootstrap

Description

Implements key components for the wild bootstrap of the hqm estimator in preparation for obtaining confidence bands.

Usage

```
prep_boot(g_xt, alpha, Ni, Yi, size_s_grid, br_X, br_s, t, b, int_X, x, n)
```

Arguments

| | |
|--------------------------|--|
| <code>g_xt</code> | A vector obtained by <code>g_xt</code> . |
| <code>alpha</code> | A vector of the marker only hazard on the marker grid obtained by <code>get_alpha</code> . |
| <code>Ni</code> | A matrix made by <code>make_Ni</code> indicating the occurrence. |
| <code>Yi</code> | A matrix made by <code>make_Yi</code> indicating the exposure. |
| <code>size_s_grid</code> | Size of the time grid. |
| <code>br_X</code> | Vector of grid points for the marker values. |
| <code>br_s</code> | Time value grid points that will be used in the evaluation. |
| <code>t</code> | Numeric value of the time the function should be evaluated. |
| <code>b</code> | Bandwidth. |
| <code>int_X</code> | Position of the linear interpolated marker values on the marker grid. |
| <code>x</code> | Numeric value of the last observed marker value. |
| <code>n</code> | Number of individuals. |

Details

The function implements

$$A_B(t) = \frac{1}{\sqrt{n}} \sum_{i=1}^n \int_0^T \hat{g}_{i,t,x_*}(X_i(s)) V_i \{dN_i(s) - \hat{\alpha}_i(X_i(s)) Z_i(s) ds\},$$

and

$$B_B(t) = \frac{1}{\sqrt{n}} \sum_{i=1}^n V_i \{ \hat{\Gamma}(t, x_*)^{-1} W_i(t, x_*) - \hat{h}_{x_*}(t) \},$$

where $V \sim N(0, 1)$,

$$W_i(t) = \int_0^T \hat{\alpha}_i(X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x_*, X_i(s)) ds,$$

and

$$\hat{\Gamma}(t, x) = \frac{1}{n} \sum_{i=1}^n \int_0^{T-t} Z_i(t+s) Z_i(s) K_b(x, X_i(s)) ds,$$

with Z being the exposure and X the marker.

Value

A list of 5 items. The first two are vectors for calculating A_B and the third one a vector for B_B . The 4th one is the value of the hqm estimator that can also be obtained by `h_xt` and the last one is the value of Γ .

Prepare for Cross validation bandwidth selection

Description

Implements the calculation of the hqm estimator on cross validation data sets. This is a preparation for the cross validation bandwidth selection technique for future conditional hazard rate estimation based on marker information data.

Usage

```

prep_cv(data, data.id, marker_name, event_time_name = 'years',
        time_name = 'year', event_name = 'status2', n, I, b)

```

Arguments

| | |
|------------------------------|---|
| <code>data</code> | A data frame of time dependent data points. Missing values are allowed. |
| <code>data.id</code> | An id data frame obtained from to_id . |
| <code>marker_name</code> | The column name of the marker values in the data frame data . |
| <code>event_time_name</code> | The column name of the event times in the data frame data . |
| <code>time_name</code> | The column name of the times the marker values were observed in the data frame data . |
| <code>event_name</code> | The column name of the events in the data frame data . |
| <code>n</code> | Number of individuals. |
| <code>I</code> | Number of observations leave out for a K cross validation. |
| <code>b</code> | Bandwidth. |

Details

The function splits the data set via `dataset_split` and calculates for every splitted data set the hqm estimator

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - X_i(s)) ds},$$

for all x on the marker grid and t on the time grid, where X is the marker, Z is the exposure and $\alpha(z)$ is the marker-only hazard, see `get_alpha` for more details.

Value

A list of matrices for every cross validation data set with $\hat{h}_x(t)$ for all x on the marker grid and t on the time grid.

Prepare for Cross validation index parameter selection

Description

Implements the calculation of the hqm estimator on cross validation data sets. This is a preparation for the cross validation index selection technique for future conditional hazard rate estimation based on marker information data.

Usage

```

prep_cv2(in.par, data, data.id, marker_name1, marker_name2, event_time_name = 'years',
         time_name = 'year', event_name = 'status2', n, I, b)

```

Arguments

| | |
|---------------------------|--|
| <code>in.par</code> | Vector of candidate indexing values. |
| <code>data</code> | A data frame of time dependent data points. Missing values are allowed. |
| <code>data.id</code> | An id data frame obtained from <code>to_id</code> . |
| <code>marker_name1</code> | The column name of the marker values in the data frame <code>data</code> . |

| | |
|-----------------|---|
| marker_name2 | The column name of the marker values in the data frame data . |
| event_time_name | The column name of the event times in the data frame data . |
| time_name | The column name of the times the marker values were observed in the data frame data . |
| event_name | The column name of the events in the data frame data . |
| n | Number of individuals. |
| I | Number of observations leave out for a K cross validation. |
| b | Bandwidth. |

Details

The function splits the data set via [dataset_split](#) and calculates for every splitted data set the hqm estimator

$$\hat{h}_x(t) = \frac{\sum_{i=1}^n \int_0^T \hat{\alpha}_i(\theta_0^T X_i(t+s)) Z_i(t+s) Z_i(s) K_b(x - \theta_0^T X_i(s)) ds}{\sum_{i=1}^n \int_0^T Z_i(t+s) Z_i(s) K_b(x - \theta_0^T X_i(s)) ds},$$

for all x on the marker grid and t on the time grid, where X is the marker, Z is the exposure and $\alpha(z)$ is the marker-only hazard, see [get_alpha](#) for more details.

Value

A list of matrices for every cross validation data set with $\hat{h}_x(t)$ for all x on the marker grid and t on the time grid.

Q1

Bandwidth selection score Q1

Description

Calculates a part for the K-fold cross validation score.

Usage

Q1(h_xt_mat, int_X, size_X_grid, n, Yi)

Arguments

| | |
|--------------------------|---|
| <code>h_xt_mat</code> | A matrix of the estimator for the future conditional hazard rate for all values x and t . |
| <code>int_X</code> | Vector of the position of the observed marker values in the grid for marker values. |
| <code>size_X_grid</code> | Numeric value indicating the number of grid points for marker values. |
| <code>n</code> | Number of individuals. |
| <code>Yi</code> | A matrix made by <code>make_Yi</code> indicating the exposure. |

Details

The function implements

$$Q_1 = \sum_{i=1}^N \int_0^T \int_s^T Z_i(t) Z_i(s) \hat{h}_{X_i(s)}^2(t-s) dt ds,$$

where \hat{h} is the hqm estimator, Z the exposure and X the marker.

Value

A value of the score Q_1 .

Quantile.Index.CIs *Compute Quantile Pointwise Confidence Intervals for for the Indexed Hazard Rate Estimate*

Description

Computes quantile-bootstrap confidence intervals and its symmetric counterparts for the hazard rate, log-hazard rate, and back-transformed (from log scale) hazard rate functions, based on the indexed hazard estimator.

Usage

```
Quantile.Index.CIs(B, n.est.points, Mat.boot.haz.rate, time.grid, hqm.est, a.sig)
```

Arguments

| | |
|-------------------|--|
| B | Integer. Number of bootstrap replications. |
| n.est.points | Integer. Number of estimation points at which the indexed hazard estimates and confidence intervals are evaluated. |
| Mat.boot.haz.rate | A matrix of bootstrap estimated hazard rates with dimensions n.est.points × B, where each column corresponds to one bootstrap replicate. |
| time.grid | Numeric vector of length n.est.points: the grid points at which the indexed hazard estimates and confidence intervals are calculated. |
| hqm.est | Indexed hazard estimator, calculated at the grid points time.grid and using the original sample. |
| a.sig | The significance level (e.g., 0.05) which will be used in computing the confidence intervals. |

Details

This function computes several forms of pivot confidence intervals for indexed hazard rate estimates. Set $k_{\alpha/2} = \hat{h}_x^{[\alpha/2]}(t) - \hat{h}_x(t)$ and $k_{1-\alpha/2} = \hat{h}_x^{[1-\alpha/2]}(t) - \hat{h}_x(t)$ where $\hat{h}_x^{[\alpha/2]}(t)$ is the $\alpha/2$ quantile of $\hat{h}_x^{(j)}(t)$, $j = 1, \dots, B$, obtained by ordering the bootstrap estimators in ascending order and selecting the $\alpha/2$ -th ordered value. For example, for $B = 1000$ bootstrap iterations and $\alpha = 0.05$, $\hat{h}_x^{[\alpha/2]}(t)$ will be the 25th smallest out of the 1000 values $\hat{h}_x^{(j)}(t)$, $j = 1, \dots, 1000$. Also denote with $\bar{k}_{1-\alpha}$ the $1 - \alpha$ quantile of

$$|\hat{h}_x^{(j)}(t) - \hat{h}_x(t)|, j = 1, \dots, B.$$

Then, the quantile bootstrap CI for $\hat{h}_x(t)$ is given by

$$\left(\hat{h}_x(t) - k_{1-\alpha/2}, \hat{h}_x(t) - k_{\alpha/2} \right).$$

The symmetric quantile CI (basic CI) is

$$\left(\hat{h}_x(t) - \bar{k}_{1-\alpha}, \hat{h}_x(t) + \bar{k}_{1-\alpha} \right).$$

The confidence intervals for the logarithm of the hazard rate function are defined as follows. First set $k_{\alpha/2}^L = \hat{L}_x^{[\alpha/2]}(t) - \hat{L}_x(t)$ and $k_{1-\alpha/2}^L = \hat{L}_x^{[1-\alpha/2]}(t) - \hat{L}_x(t)$.

Also denote with $\bar{k}_{1-\alpha}^L$ the $1 - \alpha$ quantile of $|\hat{L}_x^{(j)}(t) - \hat{L}_x(t)|$, $j = 1, \dots, B$. For the log hazard function $L_x(t)$ we have the quantile confidence interval is

$$\left(\hat{L}_x(t) - k_{1-\alpha/2}^L, \hat{L}_x(t) - k_{\alpha/2}^L \right).$$

The corresponding symmetric quantile CI for the log hazard is

$$\left(\hat{L}_x(t) - \bar{k}_{1-\alpha}^L, \hat{L}_x(t) + \bar{k}_{1-\alpha}^L \right).$$

These confidence intervals are transformed back to confidence intervals for the hazard rate function $h_x(t)$:

$$\left(\hat{h}_x(t)e^{-k_{1-\alpha/2}^L}, \hat{h}_x(t)e^{-k_{\alpha/2}^L} \right).$$

The corresponding symmetric confidence interval is

$$\left(\hat{h}_x(t)e^{-\bar{k}_{1-\alpha}^L}, \hat{h}_x(t)e^{\bar{k}_{1-\alpha}^L} \right).$$

Note: The bootstrap matrix `Mat.boot.haz.rate` is assumed to contain estimates produced using the same time grid as `time.grid` and the same estimator used to generate `hqm.est`.

Value

A data frame with the following columns:

| | |
|--------------------------|---|
| time | The evaluation grid points. |
| est | Indexed hazard rate estimator hqm.est. |
| downci, upci | Lower and upper endpoints of basic quantile CIs. |
| docisym, upcisym | Lower and upper endpoints of symmetric quantile CIs. |
| logdoci, logupci | Lower and upper endpoints of quantile CIs on the log-scale. |
| logdocisym, logupcisym | Symmetric log-scale CIs. |
| log.est | The logarithm of the indexed hazard rate estimate, $\log(\text{hqm.est})$. |
| tLogDoCI, tLogUpCI | Transformed-log CIs based on $2 \cdot \log(\text{hqm.est}) - \log\text{-quantiles}$. |
| tSymLogDoCI, tSymLogUpCI | Symmetric transformed-log CIs. |

```

R_K

Bandwidth selection score R

Description

Calculates a part for the K-fold cross validation score.

Usage

```
R_K(h_xt_mat_list, int_X, size_X_grid, Yi, Ni, n)
```

Arguments

| | |
|----------------------------|--|
| <code>h_xt_mat_list</code> | A list of matrices for all cross validation data sets. Each matrix contains the estimator with the future conditional hazard rate for all values x and t and the respected data set. |
| <code>int_X</code> | Vector of the position of the observed marker values in the grid for marker values. |
| <code>size_X_grid</code> | Numeric value indicating the number of grid points for marker values. |
| <code>Yi</code> | A matrix made by <code>make_Yi</code> indicating the exposure. |
| <code>Ni</code> | A matrix made by <code>make_Ni</code> indicating the occurrence. |
| <code>n</code> | Number of individuals. |

Details

The function implements the estimator

$$\hat{R}_K = \sum_{j=1}^K \sum_{i \in I_j} \int_0^T g_i^{-I_j}(t) dN_i(t),$$

where $\hat{g}_i^{-I_j}(t) = \int_0^t Z_i(s) \hat{h}_{X_i(s)}^{-I_j}(t-s) ds$, and \hat{h}^{-I_j} is estimated without information from all counting processes i with $i \in I_j$. This function estimates

$$R = \sum_{i=1}^N \int_0^T \int_s^T Z_i(t) Z_i(s) \hat{h}_{X_i(s)}(t-s) h_{X_i(s)}(t-s) dt ds.$$

where \hat{h} is the hqm estimator, Z the exposure and X the marker.

Value

A matrix with $\hat{g}_i^{-I_j}(t)$ for all individuals i and time grid points t .

StudentizedBwB.Index.CIs

Compute Studentized Double Bootstrap Pointwise Confidence Intervals for the Indexed Hazard Rate Estimate

Description

Computes bootstrap confidence intervals—studentized (double bootstrap) and its symmetric versions for the hazard rate, log-hazard rate, and back-transformed (from the log scale) hazard rate functions, based on the indexed hazard estimator.

Usage

```
StudentizedBwB.Index.CIs(n.est.points, all.mat, time.grid, hqm.est, a.sig)
```

Arguments

| | |
|--------------|--|
| n.est.points | Integer. Number of estimation points at which the indexed hazard estimates and confidence intervals are evaluated. |
| all.mat | A list of matrices of bootstrap estimated hazard and log hazard rates with dimensions n.est.points \times B, where each column corresponds to one bootstrap replicate. |
| time.grid | Numeric vector of length n.est.points: the grid points at which the indexed hazard estimates and confidence intervals are calculated. |
| hqm.est | Indexed hazard estimator, calculated at the grid points time.grid and using the original sample. |
| a.sig | The significance level (e.g., 0.05) which will be used in computing the confidence intervals. |

Details

This function computes several forms of studentized confidence intervals for the indexed hazard rate function. First, for each bootstrap iteration $j = 1, \dots, B$ we construct estimators of the standard deviation, denoted by $\hat{\sigma}_j^2$ as follows: each bootstrap sample is itself bootstrapped, say B_1 times, we estimate the corresponding B_1 index parameters $\hat{\theta}_{j,k} = (\hat{\theta}_{1,j,k}, \hat{\theta}_{2,j,k}), k = 1, \dots, B_1$, and use them to calculate the corresponding hazard estimators $\hat{h}_x^{(j,k)}(t), k = 1, \dots, B_1$. Finally we calculate $\hat{\sigma}_j^2$ as the sample variance of $\hat{h}_x^{(j,1)}(t), \dots, \hat{h}_x^{(j,B_1)}(t)$. Let $k_{\alpha/2}^s, k_{1-\alpha/2}^s$ and $\bar{k}_{1-\alpha}^s$ be respectively the $\alpha/2, 1 - \alpha/2$ and $1 - \alpha$ quantiles of

$$\frac{|\hat{h}_x^{(j)}(t) - \hat{h}_x(t)|}{\hat{\sigma}_j}, j = 1, \dots, B.$$

Given the bootstrap estimators $\hat{h}_x^{(j)}(t), j = 1, \dots, B$, the estimator of the original data set $\hat{h}_x(t)$ and the quantiles $k_{\alpha/2}^s, k_{1-\alpha/2}^s$ and $\bar{k}_{1-\alpha}^s$, the studentized (double bootstrap) confidence interval (CI) for $\hat{h}_x(t)$ is given by

$$\left(\hat{h}_x(t) - \hat{\sigma} k_{1-\alpha/2}^s, \hat{h}_x(t) - \hat{\sigma} k_{\alpha/2}^s \right).$$

The symmetric studentized confidence interval (CI) for $\hat{h}_x(t)$ defined by

$$\left(\hat{h}_x(t) - \hat{\sigma} \bar{k}_{1-\alpha}^s, \hat{h}_x(t) + \hat{\sigma} \bar{k}_{1-\alpha}^s \right).$$

For the confidence intervals for the logarithm of the hazard rate function first set $k_{\alpha/2}^{L,s}, k_{1-\alpha/2}^{L,s}$ and $\bar{k}_{1-\alpha}^{L,s}$ be the $\alpha/2, 1 - \alpha/2$ and $1 - \alpha$ quantile of $|\hat{L}_x^{(j)}(t) - \hat{L}_x(t)|/\hat{\sigma}_j, j = 1, \dots, B$.

The studentized (double bootstrap) CI confidence interval for the logarithm of the hazard rate function is

$$\left(\hat{L}_x(t) - \hat{\sigma} k_{1-\alpha/2}^{L,s}, \hat{L}_x(t) - \hat{\sigma} k_{\alpha/2}^{L,s} \right).$$

Its symmetric studentized (double bootstrap) CI for the log hazard is

$$\left(\hat{L}_x(t) - \hat{\sigma} \bar{k}_{1-\alpha}^{L,s}, \hat{L}_x(t) + \hat{\sigma} \bar{k}_{1-\alpha}^{L,s} \right).$$

These confidence intervals are transformed back to yield the following confidence intervals for the hazard rate function $h_x(t)$:

$$\left(\hat{h}_x(t) e^{-\hat{\sigma} \bar{k}_{1-\alpha/2}^{L,s}}, \hat{h}_x(t) e^{-\hat{\sigma} \bar{k}_{\alpha/2}^{L,s}} \right),$$

and the symmetric version

$$\left(\hat{h}_x(t) e^{-\hat{\sigma} \bar{k}_{1-\alpha}^{L,s}}, \hat{h}_x(t) e^{\hat{\sigma} \bar{k}_{1-\alpha}^{L,s}} \right).$$

Note: The bootstrap matrix `Mat.boot.haz.rate` is assumed to contain estimates produced using the same time grid as `time.grid` and the same estimator used to generate `hqm.est`.

Value

A data frame with the following columns:

| | |
|---------------------------------------|--|
| <code>time</code> | The evaluation grid points. |
| <code>est</code> | Indexed hazard rate estimator <code>hqm.est</code> . |
| <code>downci, upci</code> | Lower and upper endpoints of basic studentized CIs. |
| <code>docisym, upcisym</code> | Lower and upper endpoints of symmetric CIs. |
| <code>logdoci, logupci</code> | Lower and upper endpoints of studentized CIs on the log-scale. |
| <code>logdocisym, logupcisym</code> | Symmetric log-scale CIs. |
| <code>log.est</code> | The logarithm of the indexed hazard rate estimate, <code>log(hqm.est)</code> . |
| <code>tLogDoCI, tLogUpCI</code> | Transformed-log CIs based on $2 * \log(hqm.est) - \log$ -quantiles. |
| <code>tSymLogDoCI, tSymLogUpCI</code> | Symmetric transformed-log CIs. |

timeROC

*Time-dependent ROC curve estimation***Description**

Inverse Probability of Censoring Weighting (IPCW) estimation of Cumulative/Dynamic time-dependent ROC curve. The function works in the usual survival setting as well as in the competing risks setting. Computation of the iid-representation of areas under time-dependent ROC curves is implemented. This enables computation of inference procedures: Confidence intervals and tests for comparing two AUCs of two different markers measured on the same subjects.

Usage

```

timeROC(T, delta, marker, other_markers = NULL, cause,
        weighting = "marginal", times, ROC = TRUE, iid = FALSE)

```

Arguments

| | |
|---------------|---|
| T | The vector of (censored) event-times. |
| delta | The vector of event indicators at the corresponding value of the vector T. Censored observations must be denoted by the value 0. |
| marker | The vector of the marker values for which we want to compute the time-dependent ROC curves. Without loss of generality, the function assumes that larger values of the marker are associated with higher risks of events. If lower values of the marker are associated with higher risks of events, then reverse the association adding a minus to the marker values. |
| other_markers | A matrix that contains values of other markers that we want to take into account for computing the inverse probability of censoring weights. The different columns represent the different markers. This argument is optional, and ignored if method="marginal". Default value is other_markers=NULL. |
| cause | The value of the event indicator that represents the event of interest for which we aim to compute the time-dependent ROC curve. Without competing risks, it must be the value that indicates a non-censored observation (usually 1). With competing risks, subjects can undergo different type of events; then, it must be the value corresponding to the event of interest, for which we aim to compute the ROC curve (usually 1 or 2). |

| | |
|-----------|--|
| weighting | The method used to compute the weights. <code>weighting="marginal"</code> uses the Kaplan-Meier estimator of the censoring distribution. <code>weighting="cox"</code> and <code>weighting="aalen"</code> model the censoring by the Cox model and the additive Aalen model respectively. Default value is <code>weighting="marginal"</code> . |
| times | The vector of times points "t" at which we want to compute the time-dependent ROC curve. If vector <code>times</code> contains only a single value, then value zero is added. |
| ROC | A logical value that indicates if we want to save the estimates of sensitivities and specificities. Default value is <code>ROC = TRUE</code> . |
| iid | A logical value that indicates if we want to compute the iid-representation of the area under time-dependent ROC curve estimator. <code>iid = TRUE</code> is required for computation of all inference procedures (Confidence intervals or test for comparing AUCs). For large sample size (greater than 2000, say) and/or large length of vector <code>times</code> , the computation of the iid representations might be time-consuming. Default value is <code>iid = FALSE</code> . |

Details

This function computes Inverse Probability of Censoring Weighting (IPCW) estimates of Cumulative/Dynamic time-dependent ROC curve. By definition, time-dependent ROC curve intrinsically depends on the definitions of time-dependent cases and controls.

Let T_i denote the event time of the subject i .

Without competing risks : A case is defined as a subject i with $T_i \leq t$. A control is defined as a subject i with $T_i > t$.

With competing risks : In this setting, subjects may undergo different type of events, denoted by δ_i in the following. Let suppose that we are interested in the event $\delta_i = 1$. Then, a case is defined as a subject i with $T_i \leq t$ and $\delta_i = 1$. With competing risks, two definitions of controls were suggested: **(i)** a control is defined as a subject i that is free of any event, i.e with $T_i > t$, and **(ii)** a control is defined as a subject i that is not a case, i.e with $T_i > t$ or with $T_i \leq t$ and $\delta_i \neq 1$. For all outputs of this package, objects named with `_1` refer to definition **(i)**. For instance `AUC_1` or `se_1` refer to time-dependent area under the ROC curve and its estimated standard error according to the definition **(i)**. Objects named with `_2` refer to definition **(ii)**.

Value

Object of class "ipcwsurvivalROC" or "ipcwcompetingrisksROC", depending on if there is competing risk or not, that is a list. For these classes, there are `print`, `plot` and `confint` methods. Most objects that they contain are similar, but some are specific to each class.

Specific objects of class "ipcwsurvivalROC" :

- `AUC` : vector of time-dependent AUC estimates at each time points.
- `TP` : matrix of time-dependent True Positive fraction (sensitivity) estimates.
- `FP` : matrix of time-dependent False Positive fraction (1-specificity) estimates.

Specific objects of class "ipcwcompetingrisksROC" :

- `AUC_1` : vector of time-dependent AUC estimates at each time points with definition **(i)** of controls (see Details).

- AUC_2 : vector of time-dependent AUC estimates at each time points with definition **(ii)** of controls (see Details).
- TP : matrix of time-dependent True Positive fraction (sensitivity) estimates.
- FP_1 : matrix of time-dependent False Positive fraction (1-specificity) estimates with definition **(i)** of controls (see Details).
- FP_2 : matrix of time-dependent False Positive fraction (1-specificity) estimates with definition **(ii)** of controls (see Details).

Objects common to both classes :

- times : the time points for which the time-dependent ROC curves were computed.
- weights : a object of class "IPCW", containing all informations about the weights. See `ipcw` function of pec package.
- computation_time : the total computation time.
- CumulativeIncidence : the vector of estimated probabilities of being a case at each time points.
- survProb : the vector of estimated probabilities of being event-free at each time points.
- Stats : a matrix containing descriptive statistics at each time points (like numbers of observed cases or censored observations before each time points).
- iid : the logical value of parameter iid used in argument.
- n : the sample size, after having omitted missing vaues.
- inference : a list that contains, among other things, iid-representations and estimated standard errors of the estimators, and that is used for computation of comparison tests and confidence intervals.
- computation_time : the computation time, in seconds.

|--------------------|-------------------------|
| <code>to_id</code> | <i>Event data frame</i> |
|--------------------|-------------------------|

Description

Creates a data frame with only one entry per individual from a data frame with time dependent data. The resulting data frame focusses on the event time and the last observed marker value.

Usage

```
to_id(data_set)
```

Arguments

`data_set` A data frame of time dependent data points. Missing values are allowed.

Details

The function `to_id` uses a data frame of time dependent marker data to create a smaller data frame with only one entry per individual, the last observed marker value and the event time. Note that the column indicating the individuals must have the name `id`. Note also that this data frame is similar to `pbc2.id` from the JM package with the difference that the last observed marker value instead of the first one is captured.

Value

A data frame with only one entry per individual.

Examples

```
data_set.id = to_id(pbc2)
```
