

Package ‘Pade’

May 7, 2026

Type Package

Title Padé Approximant Coefficients

Version 1.1.0

Date 2026-03-25

Description Given a vector of Taylor series coefficients of sufficient length as input, the function returns the numerator and denominator coefficients for the Padé approximant of appropriate order (Baker, 1975) <ISBN:9780120748556>.

License GPL (>= 2) | BSD_2_clause + file LICENSE

Pade *Padé Approximant Coefficients*

Description

Given Taylor series coefficients a_n from $n = 0$ up to $n = T$, the function will calculate the Padé $[L/M]$ approximant coefficients so long as $L + M \leq T$.

Usage

`Pade(L, M, A, method = c("qr", "solve"), tol = 1e-7)`

Arguments

L **numeric**; scalar order of Padé numerator
M **numeric**; scalar order of Padé denominator
A **numeric**; vector of Taylor series coefficients, starting at x^0
method **character**; selects linear-equation solver algorithm. `qr` is more robust to ill-conditioned matrices. `solve` is faster.
tol **numeric**; the tolerance passed to `qr.solve`. Defaults to $1e-7$, the default value in `qr.solve`.

Details

As the Taylor series expansion is the “best” polynomial approximation to a function, the Padé approximants are the “best” rational function approximations to the original function. The Padé approximant often has a wider radius of convergence than the corresponding Taylor series, and can even converge where the Taylor series does not. This makes it very suitable for computer-based numerical analysis.

The $[L/M]$ Padé approximant to a Taylor series $A(x)$ is the quotient

$$\frac{P_L(x)}{Q_M(x)}$$

where $P_L(x)$ is of order L and $Q_M(x)$ is of order M . In this case:

$$A(x) - \frac{P_L(x)}{Q_M(x)} = \mathcal{O}(x^{L+M+1})$$

When q_0 is defined to be 1, there is a unique solution to the system of linear equations which can be used to calculate the coefficients.

The function accepts a vector A of length $T + 1$, composed of the a_n of the of truncated Taylor series

$$A(x) = \sum_{j=0}^T a_j x^j$$

and returns a list of two elements, Px and Qx, the Padé numerator and denominator coefficients respectively, as long as $L + M \leq T$.

Value

Pade returns a list with two entries:

Px	Coefficients of the numerator polynomial starting at x^0 .
Qx	Coefficients of the denominator polynomial starting at x^0 .

See Also

This package provides similar functionality to the pade function in the **pracma** package. However, it does not allow computation of coefficients beyond the supplied Taylor coefficients and it expects its input and provides its output in ascending—instead of descending—order.

See the **minimaxApprox** package for polynomial and rational minimax approximations to functions.

Examples

```
A <- 1 / factorial(0:10) ## Taylor sequence for e^x up to x^{10} around x_0 = 0
Z <- Pade(5, 5, A)
print(Z) ## Padé approximant of order [5 / 5]
x <- -.01 ## Test value
Actual <- exp(x) ## Proper value
print(Actual, digits = 16)
Estimate <- sum(Z[[1L]] * x ^ (seq_along(Z[[1L]]) - 1)) /
  sum(Z[[2L]] * x ^ (seq_along(Z[[2L]]) - 1))
print(Estimate, digits = 16) ## Approximant value
all.equal(Actual, Estimate)
```
