Package 'RSiena'

May 7, 2026

Encoding UTF-8

Type Package

Title Siena - Simulation Investigation for Empirical Network Analysis

Version 1.6.6

Date 2026-04-20

Maintainer Christian Steglich <c.e.g.steglich@rug.nl>

Depends R (>= 4.5.0)

Imports Matrix, lattice, parallel, MASS, methods, xtable, network

Suggests tools, codetools, tcltk

SystemRequirements GNU make

Description The main purpose of this package is to perform simulation-based estimation of stochastic actor-oriented models for longitudinal network data collected as panel data. Dependent variables can be single or multivariate networks, which can be directed, non-directed, or two-mode; and associated actor variables.
There are also functions for testing parameters and checking goodness of fit.
An overview of these models is given in Snijders (2017), <doi:10.1146/annurev-statistics-060116-054035>.

Contents

Description

Fits statistical models to longitudinal sets of networks, and to longitudinal sets of networks and behavioral variables. Not only one-mode networks but also two-mode networks and multivariate networks are allowed. The models are stochastic actor-oriented models, described in Snijders (2017).

Recent versions of the package are distributed through GitHub, see https://github.com/stocnet/rsiena/.

Bug reports can be submitted at https://github.com/stocnet/rsiena/issues.

Details

The main flow of operations of this package is as follows.

Data objects can be created from matrices and vectors using as_dependent_rsiena, as_covariate_rsiena, possibly as_composition_rsiena, and finally make_data_rsiena.

Effects are selected using an sienaEffects object, which can be created using make_specification and may be further specified by set_effect, and set_interaction.

Control of the model family, the estimation algorithm, and the output produced requires control objects that define the settings of the algorithm, and which can be created by set_algorithm_saom, set_model_saom, and set_output_saom.

Function siena is used to fit a model. Function test_gof can be used for studying goodness of fit.

Version 1.6 has established an overhaul of the function names used, while retaining the old function names for backward compatibility.

A general introduction to the method is available in the tutorial paper Snijders, van de Bunt, and Steglich (2010). Next to the help pages, more detailed help is available in the manual (see below) and a lot of information is at the website (also see below).

Package:	RSiena
Type:	Package
Version:	1.6.4

myalgo <- set_algorithm_saom(nsub=2, n3=100, seed=1291)
```

```
# nsub=2, n3=100 is used here for having a brief computation, not for practice.
(ans <- siena(mydata, effects=myeff, control_algo=myalgo,
                                          silent=TRUE, batch=TRUE))
summary(ans)
```

`allEffects` *Internal data frame used to construct effect objects.*

Description

This data frame is used internally to construct effect objects.

Usage

```
data(allEffects)
```

Format

A data frame with values for the following 23 variables.

`effectGroup` a character vector

`effectName` a character vector

`functionName` a character vector

`shortName` a character vector

`endowment` a logical vector

`interaction1` a character vector

`interaction2` a character vector

`type` a character vector

`basicRate` a logical vector

`include` a logical vector

`randomEffects` a logical vector

`fix` a logical vector

`test` a logical vector

`timeDummy` a character vector, default ","

`initialValue` a numeric vector

`parm` a numeric vector

`functionType` a character vector

`period` a character vector

`rateType` a character vector

`untrimmedValue` a numeric vector

`effect1` a logical vector

`effect2` a logical vector

`effect3` a logical vector

`interactionType` a character vector

`local` a logical vector

`setting` Settings name: '' (no settings), 'primary', 'universal' or the name of the defining covariate.

Details

Used to define effects. Not for general user use.

`as_composition_rsiena` *Functions to create a Siena composition change object*

Description

Used to create a list of events describing the changes over time of a Siena actor set.
The functions `as_composition_rsiena` and `sienaCompositionChange`
are identical; the same holds for `as_composition_file_rsiena` and
`sienaCompositionChangeFromFile`. The first of these names are preferred, the others are kept for backward compatibility.

Usage

```
as_composition_rsiena(changelist, nodeSet = "Actors", option = 1)
as_composition_file_rsiena(filename, nodeSet = "Actors",
    fileobj=NULL, option = 1)

sienaCompositionChange(changelist, nodeSet = "Actors", option = 1)
sienaCompositionChangeFromFile(filename, nodeSet = "Actors",
    fileobj=NULL, option = 1)
```

Arguments

`changelist`	A list with an entry for each actor in the node set. Each entry a vector of numbers (may be as characters) indicating intervals during which the corresponding actor was present. Each entry must have an even number of digits. The actor is assumed to be present from the first to the second, third to fourth, etc., time points.
`filename`	Name of file containing change information. One line per actor, each line a series of space delimited numbers indicating intervals.
`fileobj`	The result of `readLines` on filename.

`nodeSet` Character string containing the name of a Siena node set. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.

`option` Integer controlling the processing of the tie variables for the actors not currently present. Values (default is 1)

1. 0 before entry, final value carried forward after leaving, and used for calculating statistics in Method of Moments estimation
2. 0 before entry, missing after (final value carried forward, but treated as missing)
3. missing whenever not in the network. Previous values will be used where available, but always treated as missing values.
4. Convert to structural zeros (not available at present).

Details

If there is a composition change object for the first node set in the data object, then this will be used in estimation by the Method of Moments to make actors active (able to send and receive ties) only for the time intervals when this is indicated in the composition change object. This is done according to the procedure of Huisman and Snijders (2003). See the manual for further details.
For bipartite networks, composition change objects for the second node set have no effect and will lead to an error message.
For `M` waves, time starts at 1 and ends at `M`; so all numbers must be between 1 and the number of waves (bounds included). Intervals are treated as closed at each end. For example, an entry `(2, 4)` means that the actor corresponding to this entry arrived at wave 2 and left at wave 4, but did give valid date for both of these waves. An entry `(1.01, 2.99)` means that the actor arrived just after wave 1 and left just before wave 3, and gave valid data only for wave 2. An entry `(1, 2), (3.5, 4)` means that the actor was there at the start and left at wave 2 (giving valid data for wave 2), came back halfway between waves 3 and 4, and gave valid data still at wave 4; if there would be more than 4 waves in the data set, this entry would also mean that the actor left at wave 4.
Function `as_composition_rsiena` reads input from a list,
and `as_composition_file_rsiena` from a file. Further, they do the same.
For data sets including a composition change object, estimation by Method of Moments is forced to be unconditional, overriding the specification in the `sienaAlgorithm` object.

Value

An object of class "compositionChange", a list of numeric vectors, with attributes:

`NodeSet` Name of node set

`Option` Option

        quote=FALSE)
## file will be
## 1 3
## 1.4 2.5
compChange <- as_composition_file_rsiena("cc.dat")

## End(Not run)
```

---

as_covariate_rsiena *Function to create a covariate object*

Description

This function creates a monadic or dyadic covariate object

Usage

```
as_covariate_rsiena(val, type="monadic", centered=TRUE,
                                nodeSet="Actors", warn=TRUE,
                                imputationValues=NULL)
```

Arguments

`val`	Covariate values, given as a vector, or matrix (may be sparse, of type `"TsparseMatrix"`), or 3-dimensional array, or list of 3 sparse matrices of type `"TsparseMatrix"`; which of these structures determines the kind of covariate (see Details).
`type`	`"monadic"`, `"oneMode"` or `"bipartite"`: whether the values refer to a monadic covariate, and in case of a dyadic covariate, whether it is for a one-mode or a bipartite (two-mode) network (see Details).
`centered`	Boolean: if TRUE, then the mean value is subtracted.
`nodeSet`	Name of node set: character string; for `type="bipartite"`, referring to bipartite (two-mode) dyadic covariates, a vector of two node set names (character strings). If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
`warn`	Logical: determines whether a warning given if all values are `NA`, or all non-missing values are the same.
`imputationValues`	For monadic covariates only: Vector or matrix of covariate values of same length or dimensions as `val`, to be used for imputation of `NA` values (if any) in `val`. Must not contain any `NA`.

Details

This function determines the kind of covariate from the kind of arguments given:

- if `val` is a vector, it will be a time-constant monadic (actor) covariate;
- if `val` is a matrix and `type="monadic"`, it will be a changing monadic (actor) covariate;
- if `val` is a matrix and `type="oneMode"` or `"bipartite"`, it will be a time-constant dyadic covariate;
- if `val` is a 3-dimensional array or list of sparse matrices of type `"TsparseMatrix"`, it will be a changing dyadic covariate.

When part of a `siena` data object, the created covariate is associated with the node set `nodeSet` of this data object. In practice, the node set needs to be specified only in the case of the use of the covariate with a two-mode network.

If there are any `NA` values in `val`, and `imputationValues` is given, and the covariate is monadic, then the corresponding elements of `imputationValues` are used for imputation. If `imputationValues` is `NULL`, imputation is by the mean value. In both cases, cases with imputed values are not used for calculating target statistics (see the manual).

For changing covariates (monadic or dyadic), the values for wave `m` are supposed in the simulations to be valid in the whole period from wave `m` to wave `m+1`. If the data set has `M` waves, this means that the values, if any, for wave `M` will not be used. These values may be given or omitted as part of `val`.

The function replaces `coCovar`, `varCovar`, `coDyadCovar`, `varDyadCovar`, which now are obsolete.

Value

The covariate is returned as an object of class coCovar, varCovar, coDyadCovar, or varDyadCovar, as the case may be. This object can be used as an argument to make_data_rsiena.

See Also

make_data_rsiena, as_nodeset_rsiena; this function replaces the functions coCovar, varCovar, coDyadCovar, varDyadCovar.

Examples

```
# constant monadic covariate:
myconstcovar <- as_covariate_rsiena(s50a[,1])
senders <- as_nodeset_rsiena(50, nodeSetName="senders")
receivers <- as_nodeset_rsiena(30, nodeSetName="receivers")
senders.attribute <- as_covariate_rsiena(rep(1:10, each=5),
                                         nodeSet="senders")
receivers.attribute <- as_covariate_rsiena(rep(1:5, each=6),
                                         nodeSet="receivers")
# varying monadic covariate:
myvarcovar <- as_covariate_rsiena(s50a, type="monadic")
senders.covariate <- as_covariate_rsiena(s50a, nodeSet="senders",
                                               type="monadic")
receivers.covariate <- as_covariate_rsiena(s50s[1:30,],
                            nodeSet="receivers", type="monadic")
# constant dyadic covariate:
mydyadvar <- as_covariate_rsiena(s503, type="oneMode")
# varying dyadic covariate:
mydyadvar <- as_covariate_rsiena(array(c(s501, s502), dim=c(50, 50, 2)),
                                 type="oneMode")
# using sparse matrices for a constant dyadic covariate:
require(Matrix)
sps501 <- as(s501,"TsparseMatrix")
sps502 <- as(s502,"TsparseMatrix")
sps502r <- as(s502[1:30,],"TsparseMatrix")
spcDyadvar <- as_covariate_rsiena(sps501, type="oneMode")
spvDyadvar <- as_covariate_rsiena(list(sps501,sps502), type="oneMode")
spvDyadBipvar <- as_covariate_rsiena(list(sps501,sps502),
                   type="bipartite", nodeSet=c("senders","receivers"))
```

`as_dependent_rsiena` *Function to create a dependent variable for a Siena model*

Description

Creates a Siena dependent variable: either a network, created from a matrix or array or list of sparse matrix of triples; or a behavior variable, created from a matrix.
`as_dependent_rsiena()`, `sienaDependent()` and `sienaNet()` are identical functions. The first name is preferred, the two others are kept for backward compatibility.

Usage

```
as_dependent_rsiena(netarray,
      type=c("oneMode", "bipartite", "behavior", "continuous"),
      nodeSet="Actors", sparse=is.list(netarray),
      allowOnly=TRUE, imputationValues=NULL)

sienaDependent(netarray,
      type=c("oneMode", "bipartite", "behavior", "continuous"),
      nodeSet="Actors", sparse=is.list(netarray),
      allowOnly=TRUE, imputationValues=NULL)

sienaNet(netarray,
      type=c("oneMode", "bipartite", "behavior", "continuous"),
      nodeSet="Actors", sparse=is.list(netarray),
      allowOnly=TRUE, imputationValues=NULL)
```

Arguments

`netarray`	`type="behavior"` or `"continuous"`: matrix (actors $\times$ waves). `type="oneMode"` or `"bipartite"`: array of values or list of sparse matrices of type `"TsparseMatrix"`, see the `Matrix` package; if an array is used, it should have dimensions: for a one-mode network, $n \times n \times M$, and for a two-mode network $n \times m \times M$, where n is the number of actors, m is the number of nodes in the second mode, and M is the number of waves.
`type`	type of dependent variable, default `oneMode`.
`nodeSet`	character string naming the appropriate node set. For a bipartite network, a vector containing 2 character strings: "rows" first, then "columns".
`sparse`	logical: TRUE indicates the data is in sparse matrix format, FALSE otherwise.
`allowOnly`	logical: If TRUE, it will be detected when between any two consecutive waves the changes are non-decreasing or non-increasing, and if this is the case, this will also be a constraint for the simulations between these two waves. This is done by means of the internal parameters `uponly` and `downonly`. If FALSE, the parameters `uponly` and `downonly` always are set to FALSE, and changes in dependent variables will not be constrained to be non-decreasing or non-increasing. This also will imply that some effects are excluded because they

are superfluous in such constrained situations. This will be reported in the output of print01Report.

For normal operation when this is the case for all periods, usually TRUE is the appropriate option. When it is only the case for some of the periods, and for data sets that will be part of a multi-group object created by make_group_rsiena, FALSE usually is preferable.

imputationValues

for behavior or continuous dependent variables, a matrix with imputation values can be included that will be used instead of the default imputation values.

Details

Adds attributes so that the array or list of matrices can be used in a Siena model fit.

Value

An object of class sienaDependent. An array or (networks only) a list of sparse matrices with attributes:

netdims	Dimensions of the network or behavior variable: senders, receivers (1 for behavior), periods
type	oneMode, bipartite or behavior
sparse	Boolean: whether the network is given as a list of sparse matrices or not
nodeSet	Character string with name(s) of node set(s)
allowOnly	The value of the allowOnly parameter

Author(s)

make_data_rsiena, as_nodeset_rsiena, make_constraint.sienadata

Examples

```
mynet1 <- as_dependent_rsiena(array(c(s501, s502, s503), dim=c(50, 50, 3)))
mybeh <- as_dependent_rsiena(s50a, type="behavior")
## note that the following example works
## although the node sets do not yet exist!
mynet3 <- as_dependent_rsiena(array(c(s501, s502, s503), dim=c(50, 50, 3)),
       type="bipartite", nodeSet=c("senders", "receivers"))
## sparse matrix input
## To show this, we first go back from the adjacency matrices to edgelists.
## The manual shows one way to do this.
```

```
## Another way is to use the sparse matrix representation which internally
## indeed is an edge list:
library(Matrix)
sp501 <- as(Matrix(s501), "TsparseMatrix")
sp502 <- as(Matrix(s502), "TsparseMatrix")
sp503 <- as(Matrix(s503), "TsparseMatrix")
## If you are interested in the internal structure
## of these sparse matrices, you can request
str(sp501)
## Slot @i is the row, @j is the column, and @x the value;
## here the values all are 1.
## Slots @i and @j do not contain information about the number of nodes,
## so that is supplied additionally by @Dim.
mymatlist <- list(sp501, sp502, sp503)
mynet.sp <- as_dependent_rsiena(mymatlist)
# For a bipartite (two-mode) network:
senders <- as_nodeset_rsiena(50, nodeSetName="senders")
receivers <- as_nodeset_rsiena(30, nodeSetName="receivers")
mynet <- as_dependent_rsiena(
          array(c(s501[,1:30], s502[,1:30]), dim=c(50, 30, 2)),
          nodeSet=c("senders", "receivers"))
mynet
```

`as_nodeset_rsiena` *Function to create a node set*

Description

Creates a Siena node set which can be used as the nodes in a Siena network.
The functions `as_nodeset_rsiena` and `sienaNodeSet` are identical. The first name is preferred, the other is kept for backward compatibility.

Usage

```
as_nodeset_rsiena(n, nodeSetName="Actors", names=NULL)

sienaNodeSet(n, nodeSetName="Actors", names=NULL)
```

Arguments

`n`	integer, size of set.
`nodeSetName`	character string naming the node set.
`names`	optional character string vector of length n of the names of the nodes.

Details

This function is important for data sets having more than one node set, but not otherwise.

Value

Returns a Siena node set, an integer vector, possibly with names, plus the attributes, class equal to "as_nodeset_rsiena", and nodeSetName equal to the argument nodeSetName.

                        type="monadic", nodeSet="senders")
receivers.attribute <- as_covariate_rsiena(rep(1:5, each=6),
                        type="monadic", nodeSet="receivers")
mynet <- as_dependent_rsiena(
      array(c(s501[,1:30], s502[,1:30]), dim=c(50, 30, 2)),
      nodeSet=c("senders", "receivers"))
(mydata <- make_data_rsiena(mynet, senders.attribute, receivers.attribute,
      nodeSets=list(senders, receivers)))
```

---

coCovar *Function to create a constant covariate object*

Description

This function creates a constant covariate object from a vector.
This function now is superseded by function as_covariate_rsiena.

Usage

```
coCovar(val, centered=TRUE, nodeSet="Actors", warn=TRUE,
        imputationValues=NULL)
```

Arguments

val	Vector of covariate values
centered	Boolean: if TRUE, then the mean value is subtracted.
nodeSet	Name of node set: character string. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
warn	Logical: is a warning given if all values are NA, or all non-missing values are the same.
imputationValues	Vector of covariate values of same length as val, to be used for imputation of NA values (if any) in val. Must not contain any NA.

Details

When part of a Siena data object, the covariate is associated with the node set nodeSet of the Siena data object. In practice, the node set needs to be specified only in the case of the use of the covariate with a two-mode network.
If there are any NA values in val, and imputationValues is given, then the corresponding elements of imputationValues are used for imputation. If imputationValues is NULL, imputation is by the mean value. In both cases, cases with imputed values are not used for calculating target statistics (see the manual).

Value

Returns the covariate as an object of class "coCovar", in which form it can be used as an argument to sienaDataCreate.

Examples

```
myconstCovar <- coCovar(s50a[,1])
senders <- sienaNodeSet(50, nodeSetName="senders")
receivers <- sienaNodeSet(30, nodeSetName="receivers")
senders.attribute <- coCovar(rep(1:10, each=5), nodeSet="senders")
receivers.attribute <- coCovar(rep(1:5, each=6), nodeSet="receivers")
```

coDyadCovar *Function to create a constant dyadic covariate object*

Description

This function creates a constant dyadic covariate object from a matrix.
This function now is superseded by function as_covariate_rsiena.

Usage

```
coDyadCovar(val, centered=TRUE, nodeSets=c("Actors", "Actors"),
     warn=TRUE, sparse=inherits(val,"TsparseMatrix"),
     type=c("oneMode", "bipartite"))
```

Arguments

val	Matrix of covariate values. May be sparse, of type "TsparseMatrix".
centered	Boolean: if TRUE, then the mean value is subtracted.
nodeSets	The name of the node sets with which this covariate is associated. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
warn	Logical: is a warning given if all values are NA, or all non-missing values are the same.
sparse	Boolean: whether a sparse matrix or not.
type	oneMode or bipartite: whether the matrix refers to a one-mode or a bipartite (two-mode) network.

Details

When part of a Siena data object, the covariate is assumed to be associated with the node sets named in nodeSets of the Siena data object. The name of the associated node sets will only be checked when the Siena data object is created.

Value

Returns the covariate as an object of class "coDyadCovar", in which form it can be used as an argument to make_data_rsiena.

`edit.sienaEffects` *Allow editing of a sienaEffects object if a gui is available.*

Description

Interactive editor for an effects object. A wrapper to edit.data.frame.

Usage

```
## S3 method for class 'sienaEffects'
edit(name, ...)
```

Arguments

`name`	An object of class `sienaEffects`
`...`	For extra arguments (none used at present)

Details

Will be invoked by `fix(name)` for an object of class `sienaEffects`.

Value

The updated object. There is no backup copy, and the edits cannot be undone.

```

---

effectsDocumentation *Function to create a table of documentation of effect names, short names etc.*

Description

Produces a table of the shortnames and other information for effects, either in html or latex.

Usage

```
effectsDocumentation(effects = NULL, type = "html", display = (type=="html"),
     filename = ifelse(is.null(effects), "effects",
                                         deparse(substitute(effects))))
```

Arguments

effects	A Siena effects object, or NULL.
type	Type of output required. Valid options are "html" or "latex".
display	Boolean: should the output be displayed after creation. Only applicable to html output.
filename	Character string denoting file name.

Details

If effects=NULL, the allEffects object is written to a table, either latex or html. This table presents all the available effects present in this version of RSiena, not delimited by a particular data set. The default file name is "effects.tex" or "effects.html", respectively.

The table lists all effects, with their name, shortName, whether an endowment (and creation) effect exists, the value of an effect parameter - if any -, and the interactionType (which can be empty or: "ego" or "dyadic" for dependent network variables; "OK" for dependent behavior variables). The latter is important for knowing how the effects can be used in interaction effects. (See includeInteraction).

If an existing effects object is specified for effects, then all available effects in this effects object are listed. This table lists the name (i.e., dependent variable), effect name, shortName, type

(rate/evaluation/endowment/creation), the variables defined as `interaction1` and `interaction2` (see `includeEffects`) that specify this effect, the value of an effect parameter - if any -, and the interactionType.
The GMoM effects, which are those with `type=gmm`, are listed at the end. For these, the distinction between the fields `name` and `interaction1`, referring to the dependent and the explanatory roles of the variables, has no meaning.
The default root file name is the name of the input effects object.

Value

Nothing returned. Output files are created in the current working directory.

funnelPlot *Plot function for a list of sienaFit objects*

Description

Draws a funnel plot for a list of sienaFit objects that all have estimated the same parameter.

Usage

```
funnelPlot(anslist, k, threshold=NULL, origin=TRUE,
           plotAboveThreshold=TRUE, verbose=TRUE, ...)
```

Arguments

`anslist`	A list of object of class `sienaFit`.
`k`	The number of the parameter to be plotted.
`threshold`	threshold for standard errors: all estimations where the standard error for parameter `k` is larger than this threshold will be disregarded.

origin	Boolean: whether to include the origin in the plot, if all estimates have the same sign.
plotAboveThreshold	Boolean: whether to include the estimates for which the standard error is larger than threshold, and plot them with an asterisk at se=threshold.
verbose	Boolean: whether to report in the console all estimates omitted, because either their standard error is larger than threshold, or they were fixed.
...	For extra arguments (passed to plot).

Details

The function funnelPlot plots estimates against standard errors for a given effect k, with red reference lines added at the two-sided significance threshold 0.05. Effects for which a score test was requested are not plotted (and reported to the console if verbose).
If not all effects with number k are the same in all sienaFit objects, a warning is given. The effect name for the first object is used as the plot title.
Another funnel plot is available as print.sienaMeta.

Value

The two-column matrix of values of the plotted points is invisibly returned.

hn3401 *Network data: excerpt from "Dutch Social Behavior Data Set" of Chris Baerveldt.*

Description

Matrices N3401, N3403, N3404, N3406, and HN3401, HN3403, HN3404, HN3406 are two waves of networks for four schools (numbered 1, 3, 4, 6).

Format

Adjacency matrices for the network at two time points. The matrices with name N... are the first wave, those with name HN... are the second wave.

There is a tie from pupil i to pupil j if i says that he/she receives and/or gives emotional support from/to pupil j. The data are part of a larger data set (see source below) and were collected under the direction of Chris Baerveldt.

includeEffects *Function to include effects in a Siena model*

Description

This function can be used for model specification by modifying a Siena effects object.
This function now is superseded by set_effect.

Usage

```
includeEffects(myeff, ..., include = TRUE, name = myeff$name[1],
 type = "eval", interaction1 = "", interaction2 = "",
 fix=FALSE, test=FALSE, character=FALSE, verbose = TRUE)
```

Arguments

myeff	a Siena effects object as created by make_specification
...	short names to identify the effects which should be included or excluded.
include	Boolean. default TRUE, but can be switched to FALSE to turn off an effect.
name	Name of dependent variable (network or behavior) for which effects are being included. Defaults to the first in the effects object, which is the first dependent variable specified in sienaDataCreate.
type	Type of effects to be included: "eval", "endow", "creation", or "rate".
interaction1	Name of siena object where needed to completely identify the effects, e.g., covariate name or behavior variable name.
interaction2	Name of siena object where needed to completely identify the effects, e.g., covariate name or behavior variable name.
fix	Boolean. Are the effects to be fixed at the value stored in myeff$initialValue or not.
test	Boolean. Are the effects to be tested or not (requires fix).
character	Boolean: are the effect names character strings or not.
verbose	Boolean: should the print of altered effects be produced.

Details

Recall from the help page for make_specification that a Siena effects object (class sienaEffects or sienaGroupEffects) is a data.frame; the rows in the data frame are the effects for this data set; some of the columns/variables of the data frame are used to identify the effect, other columns/variables define how this effect is used in the estimation.

The function includeEffects operates as an interface setting the "include" column on selected rows of the effects object, to the value requested (TRUE or FALSE). The selected effects must be indicated by the arguments ..., type, and (if necessary) interaction1 and interaction2. The names interaction1 and interaction2 do not refer to interactions between effects, but to dependence

of effects on other variables in the data set. The arguments should identify the effects completely. The short names must not be set between quotes, unless you use `character=TRUE`.

Note that the internal effect parameter has a default value which differs between effects. This can be set by function `setEffect`. Also the value of `myeff$initialValue` can be set by this function. The function `setEffect` operates on the effects object in a more detailed way, but applies to one effect at the time.

Further information about Siena effects objects is given in the help page for `make_specification`.

A list of all effects available in a given effects object (e.g., `myeff`), including their names of dependent variables, effect names, short names, and values of `interaction1` and `interaction2` (if any), is obtained by executing `effectsDocumentation(myeff)`.

The input names `interaction1` and `interaction2` do not themselves refer to created interactions, but to dependence of the base effects on other variables in the data set. They are used to completely identify the effects.

Value

An updated version of the input effects object, with the `include`, `test`, and `fix` columns for one or more rows updated. Details of the rows altered will be printed.

mybeh  <- as_dependent_rsiena(s50a, type="behavior")
mydata <- make_data_rsiena(mynet, mybeh)
myeff <- make_specification(mydata)
myeff <- set_effect(myeff, avAlt, depvar="mybeh", covar1="mynet")
myeff <- set_effect(myeff, list(transTrip, outAct))
myeff
```

includeGMoMStatistics *Function to include GMoM statistics in a Siena model*

Description

This function can be used for including one or more GMoM statistics by modifying a Siena effects object.

Usage

```
includeGMoMStatistics(myeff, ..., include=TRUE,
                      depvar=myeff$name[1], covar1="", covar2="",
                      character=FALSE, verbose=TRUE)
```

Arguments

myeff	a Siena effects object as created by make_specification.
...	short names to identify the GMoM statistics which should be included or excluded.
include	Boolean; default TRUE, but can be switched to FALSE to turn off an effect.
depvar	Name of dependent variable (network or behavior) for which statistics are being included. Defaults to the first in the effects object.
covar1	Name of siena object where needed to completely identify the effects e.g. covariate name or behavior variable name.
covar2	Name of siena object where needed to completely identify the effects e.g. covariate name or behavior variable name.
character	Boolean: are the statistic names character strings or not.
verbose	Boolean: should the print of altered statistic be produced.

Details

The names covar1 and covar2 refer to the dependence of the GMoM statistics on other variables in the data set. The arguments should identify the GMoM statistic completely. The type does not have to be specified, as it is gmm for all GMoM statistiscs in the effects object.
The short names must not be set between quotes, unless you use character=TRUE.

The function includeGMoMStatistics operates as an interface setting the "include" column on selected rows of the effects object, to the value requested (TRUE or FALSE).

Value

An updated version of the input effects object, with the include column for one or more rows updated. Details of the rows altered will be printed.

---

includeTimeDummy *Function to include time dummy effects in a Siena model*

Description

This function specifies time heterogeneity for selected effects in a Siena model, by interacting them with time dummies, without explicitly using time-dependent covariates.

Usage

```
includeTimeDummy(myeff, ..., timeDummy="all", depvar=myeff$name[1],
       type="eval", covar1="", covar2="", include=TRUE, character=FALSE)
```

Arguments

myeff	A Siena effects object as created by make_specification.
...	Short names to identify the effects for which interactions with time dummies should be included or excluded. This function cannot be used for regular interaction effects.
timeDummy	Character string. Either "all" or the periods for which to create dummies (from 1 to (number of waves - 1)), space delimited.
include	Boolean. default TRUE, but can be switched to FALSE to turn off an effect.
depvar	Name of dependent network or behavioral variable for which effects are being included. Defaults to the first in the effects object.
type	Type of dummy effects to be interacted.
covar1	Name of variable where needed to completely identify the effects e.g. covariate name or behavior variable name.
covar2	Name of variable where needed to completely identify the effects e.g. covariate name or behavior variable name.
character	Boolean: are the effect names character strings or not

Details

The arguments (..., `name`, `covar1`, `covar2`) should identify the effects completely.
See `make_specification` and `effectsDocumentation` for more information about this.

This function operates by setting the `timeDummy` column on selected rows of a Siena effects object, thereby specifying interactions of the specified effect or effects with dummy variables for the specified periods. The `timeDummy` column of `myeff` will be set to include the values requested if `include=TRUE`, and to exclude them for `include=FALSE`.

For an effects object in which the `timeDummy` column of some of the included effects includes some or all period numbers, interactions of those effects with ego effects of time dummies for the indicated periods will also be estimated by `siena`. For the outdegree effect this is just the ego effect of the time dummies. If ... does not include the outdegree effect, then still this ego effect will be created, but its parameter will be fixed to 0.

An alternative to the use of `includeTimeDummy` is to define time-dependent actor covariates (dummy variables or other functions of wave number that are the same for all actors), include these in the data set through `make_data_rsiena`, and include interactions of other effects with ego effects of these time-dependent actor covariates by `set_interaction`. This is illustrated in an example in the help file for `test_time`. Using `includeTimeDummy` is easier; on the other hand, using self-defined interactions with time-dependent variables gives more control (e.g., it will allow to specify linear time dependence and test time heterogeneity for interaction effects).

Value

An updated version of `myeff`, with the `timeDummy` column for one or more rows updated. Details of the rows altered will be printed.

(ans2 <- siena(mydata, effects=myeff))

## Re-assess the time heterogeneity
tt2 <- sienaTimeTest(ans2)
summary(tt2)

## And so on..

## End(Not run)
```

`interpret_influence` *Function to construct influence tables for SAOMs*

Description

The function `influenceTable` constructs influence tables which may be helpful for the interpretation of results for network and behavior dynamics, for an estimation result represented by a `sienaFit` object created by `siena`.

Usage

```
## S3 method for class 'sienaFit'
interpret_influence(x, xd, netname, behname,
    as.matrix=FALSE, levls=NULL, levls.alt=levls,
    out.ego=1, silent=FALSE, nfirst=x$nwarm+1,
    include.endow=FALSE, include.creation=FALSE, ...)

influenceTable(x, xd, netname, behname,
    as.matrix=FALSE, levls=NULL, levls.alt=levls,
    out.ego=1, silent=FALSE, nfirst=x$nwarm+1,
    include.endow=FALSE, include.creation=FALSE)
```

Arguments

`x`	An object of class `sienaFit`, produced by a call to `siena` for a model including a behavioral dependent variable; or an object of class `sienaMeta`, produced by a call to `meta_siena`; or an object of class `sienaBayesFit`, produced by a call to `sienaBayes`.

xd	If x is of class sienaFit, a sienadata data set used to produce x. If x is of class sienaMeta or sienaBayesFit, one of the data sets used to produce x; preferable a representative one.
netname	character string: name of network dependent variable.
behname	character string: name of behavior dependent variable.
as.matrix	boolean: will the table be returned as a matrix.
levls	levels for ego.
levls.alt	levels for alter.
out.ego	presumed outdegree of ego for effects totSim and totAlt.
silent	boolean; if FALSE, the parameters taken from x are reproduced at the console.
nfirst	If x is of class sienaBayesFit: first run in posterior sample used for constructing the table.
include.endow	boolean, used only for models utilizing influence and endowment effects: by specifying include.endow=TRUE, # the sum of evaluation and endowment effects is used.
include.creation	boolean, used only for models utilizing influence and creation effects: by specifying include.creation=TRUE, # the sum of evaluation and creation effects is used.
...	Other arguments.

Details

This functions is used for constructing influence tables for the interpretation of results for network and behavior dynamics obtained with the RSiena or multiSiena packages.

In matrix form, each row corresponds to a given average behavior of the alters, to whom the focal actor (ego) is connected by an outgoing tie; the columns are the different potential values of ego's own behavior. The rows are for the values in levls.alt, the columns for the values in levls.

If levls is NULL (the default), the levels of ego's behavior are taken as the integer range of the dependent actor variable. In most applications levls.alt will be the same as levls, in which case it does not have to be specified.

The data set xd is only used to get means and ranges which are used somewhere in the effects.

This function has its own print method.
It can be plotted by package autograph.

Value

An object of class influenceTable.
This represents the joint contribution to the evaluation function of effects "linear", "quad", "avAlt", "avSim", "totAlt", "totSim", "avAttHigher", "avAttLower", "threshold", "threshold2", "threshold3", and "threshold4".
If as.matrix=TRUE, the object is a matrix; if as.matrix=FALSE (the default), it is a data frame, where the rows are all combinations of levls and levls.alt, and the columns:

alter	alter's values as a factor;

zalter	the values levls.alt
zego	the values levls
select	the value of the influence table.

This object has an attribute quad, which specifies whether the plot will be a quadratic function.

interpret_selection *Function to construct selection tables for SAOMs*

Description

The function selectionTable constructs a selection table which may be helpful for the interpretation of results for network dynamics, for an estimation result represented by a sienaFit object created by siena.

Usage

```
## S3 method for class 'sienaFit'
interpret_selection(x, xd, name, vname,
    as.matrix=FALSE,levls=NULL, levls.alt=levls,
    nfirst=x$nwarm+1, multiplier=1,
    include.endow=FALSE, include.creation=FALSE,
    silent=FALSE, ...)

selectionTable(x, xd, name, vname,
    as.matrix=FALSE,levls=NULL, levls.alt=levls,
    nfirst=x$nwarm+1, multiplier=1,
    include.endow=FALSE, include.creation=FALSE,
    silent=FALSE)
```

Arguments

x	An object of class sienaFit, produced by a call to siena for a model including a behavioral dependent variable; or an object of class sienaMeta, produced by a call to meta_siena; or an object of class sienaBayesFit, produced by a call to sienaBayes.
xd	If x is of class sienaFit, a siena data set used to produce x. If x is of class sienaMeta or sienaBayesFit, one of the data sets used to produce x; preferable a representative one.
name	character string: name of network dependent variable.
vname	character string: name of actor covariate (should be centered!).
as.matrix	boolean: will the table be returned as a matrix.
levls	levels for ego.
levls.alt	levels for alter.
nfirst	If of class sienaBayesFit: first run in posterior sample used for constructing the table.
multiplier	multiplier for the range of the actor covariate.
include.endow	boolean, used only for models utilizing selection and endowment effects: by specifying include.endow=TRUE, the sum of evaluation and endowment effects is used.
include.creation	boolean, used only for models utilizing selection and creation effects: by specifying include.creation=TRUE, the sum of evaluation and creation effects is used.
silent	boolean; if FALSE, some information is reproduced at the console.
...	Other arguments.

Details

This functions is used for constructing selection tables for the interpretation of results for network dynamics obtained with the RSiena or multiSiena packages.

In matrix form, each row corresponds to ego's value of the covariate, and each column to alter's value. The table entries are the joint contributions of covariate effects to the objective function, for this covariate and for the combinations of ego and alter values. Effects currently implemented are "altX", "altSqX", "egoX", "egoSqX", "egoXaltX", "simX", "diffX", "diffSqX", "higher", "sameX", "egoDiffX", and "egoPlusAltX".

If levls is NULL (the default), the levels of ego's behavior are taken as the integer range of the dependent actor variable. In most applications levls.alt will be the same as levls, in which case it does not have to be specified.

The multiplier is used in case the variable vname has a different natural scale, and the values for ego and alter as reported should be multiplied. The values given for levls and levls.alt are before this multiplication, i.e., they are the values as in the data set.

The data set xd is only used to get the means and similarity means which are subtracted somewhere in the effects.

This function has its own print method.
It can be plotted by package autograph.

Value

An object of class selectionTable.
If as.matrix=TRUE, this object is a matrix; if as.matrix=FALSE (the default), it is a data frame, where the rows are all combinations of levls and levls.alt, and the columns:

ego	ego's values as a factor;
vego	the values levls
valter	the values levls.alt
select	the value of the selection table.

This object has an attribute quad, which specifies whether the plot will be a quadratic function.

`interpret_size` *Functions to assess the relative importance of effects at observation moments*

Description

The function `interpret_size` computes various effect sizes for Stochastic Actor-oriented Models. As its value it returns the relative importance of effects of a SAOM according to the measure of relative importance described in Section 3.1 of Indlekofer and Brandes (2013). This is based on the influence of effects on potential tie change or behavior change decisions of individual actors at the given observation moments (waves).
Other measures useful for effect sizes are entropy-based effect sizes as in Snijders (2004) and the within-ego standard deviations of change statistics. If `getChangeStats=TRUE`, the arrays of change statistics are stored in the `sienaRI` object that is created.

It takes the data as well as the complete model specification into account. Therefore, necessary arguments are the analysed data given as a `sienadata` data object as well as the complete model specification represented either by an estimated `sienaFit` object or by the combination of a suitable parameter vector `theta` and the corresponding `sienaEffects` object.

Usage

```
## S3 method for class 'sienaFit'
interpret_size(x, data, getChangeStats=FALSE, ...)
## S3 method for class 'sienaEffects'
interpret_size(x, data, theta, getChangeStats=FALSE, ...)
## S3 method for class 'sienaRI'
print(x, printSigma=FALSE,...)
## S3 method for class 'sienaRI'
plot(x, actors = NULL, col = NULL, addPieChart = FALSE,
              radius = 1, width = NULL, height = NULL, legend = TRUE,
              legendColumns = NULL, legendHeight = NULL,
              cex.legend = NULL, cex.names = NULL,...)
```

Arguments

x	for interpret_size.sienaFit: a sienaFit object, resulting from a call of siena; for interpret_size.sienaEffects: a sienaEffects object that was used for calling siena; for print.sienaRI and plot.sienaRI: a sienaRI object resulting from a call to interpret_size.
data	siena data object representing the analyzed data and resulting from a call to make_data_rsiena.
theta	Vector of parameter values of evaluation effects included in the model. Length of theta has to be equal to the number of included evaluation effects in the effects object x.
getChangeStats	Boolean: If TRUE, an array of change statistics is added to the interpret_size object.
printSigma	Boolean: If TRUE, average within-actor standard deviations of change statistics ('sigma') are included in the print.
actors	vector of integers: set of actors to be included in the plot; if NULL, all actors.
col	Colors used in the plot. If col=NULL a default color scheme is used.
addPieChart	Boolean: If TRUE, pie charts of aggregated relative importances for the complete set of actors will be added to the plot.
radius	Radius of pie charts. Only effective if addPieCharts = TRUE.
width	Width of the plot. If width=NULL a default value is used.
height	Height of the plot. If height=NULL a default value is used.
legend	Boolean: if TRUE a legend is added to the plot. x$effectNames are used as labels.
legendColumns	Number of columns in legend. If legendColumns=NULL a default value is used. Only effective if legend=TRUE.
legendHeight	Height of legend. If legendHeight=NULL a default value is used. Only effective if legend=TRUE.
cex.legend	Specifies the relative font size of legend labels.
cex.names	Specifies the relative font size of bar graph labels.
...	Other arguments.

Details

interpret_size works only for estimation by the Method of Moments using modelType 1 (directed networks) or 2 ('forcing' model for non-directed networks). For dependent behavior variables, behModelType=1 ('standard') is assumed. It does not yet work for endowment or creation effects (i.e., included effects have to be of type eval) or rate, and also not for models with interaction effects. For two-mode (bipartite) networks as dependent variables, it works only if the number of second-mode nodes is less than the number of actors.

If there are any missing tie values in the network data set, they are imputed by initial zeros and Last Observation Carried Forward. Structural zeros and ones are replaced by NA and treated as

impossible choices in the probability vectors and ignored in the standard deviations; but the change statistics for these dyads still are given in changeStatistics (if requested).

The averages reported in the components sigmas (average across actors) and meansigmas (average across waves) are obtained by averaging at the variance level and then taking square roots.

Value

If the model contains only one dependent variable, interpret_size returns an object of class sienaRI. Otherwise, it returns a list of objects of class sienaRI, each corresponding to one dependent variable.

A returned sienaRI object stores the expected relative importances of effects of one dependent variable at observation moments as defined in Section 3.1 of Indlekofer and Brandes (2013).

A sienaRI object is a list with the following components. For the components referred to as lists themselves, these are lists corresponding to the observation moments.

- dependentVariable the name of the corresponding dependent variable.
- effectNames the names of considered effects.
- RIActors a list that contains the expected relative importances of effects for each potential actor decision at observation moments. This is equation (3) in Indlekofer and Brandes (2013).
- expectedRI a list that contains the expected relative importances of effects aggregated over all actors for each network observation. These are the averages of the actor related values in RIActors. This is equation (4) in Indlekofer and Brandes (2013).
- IActors a list that contains the expected importances of effects for each potential actor decision at observation moments. This is the numerator of equation (3) in Indlekofer and Brandes (2013).
- expectedI a list that contains the expected importances of effects aggregated over all actors in each observation. More precisely, it contains the averages of the actor related values in IActors.
- absoluteSumActors a list that contains the sum of the (unstandardized) L1-differences calculated for each potential actor decision at observation moments. This is the denominator of equation (3) in Indlekofer and Brandes (2013).
- RHActors a list that contains the degree of certainty, also called degree of determination, in the potential ministep taken by an actor at the observation moments; this is R_H(i,x) of formula (6) in Snijders (2004). The mean over actors of these degrees of certainty, given by formula (7) in Snijders (2004), is printed by the print method for interpret_size objects.
- sigma a list of effects by ego matrices of the values of the within-ego standard deviations of the change statistics.
- sigmas effects by wave matrices of averages (see above for how this is done; across actors) of sigma. These are printed if printSigma=TRUE.
- meansigmas average (see above for how this is done) over waves of sigmas.
- changeStatistics a list of arrays (effects by choices by egos) containing, for each observation wave, the values of the change statistics for making this choice, where for one-mode networks the choice is defined by the alters with alter=ego referring to 'no change', for two-mode networks the choice is defined by the second-mode nodes with the last choice referring to 'no change', and for behavior the choice is defined as going down, staying constant, or going up; this output is produced only if getChangeStats=TRUE.

- `toggleProbabilities` an array (egos by choices by waves), where "choices" are as directly above, giving the choice probabilities of ego in a ministep, when the data are as in this wave.

`interpret_size_dynamics` *Functions to assess the dynamics of relative importance of effects between observation moments*

Description

The function `interpret_size_dynamics` returns the relative importance of effects in a SAOM according to the measure of relative importance described in Indlekofer and Brandes (2013). More precisely, it returns aggregates of relative importances over simulated ministeps between observation moments as described in Section 3.2 of this paper but only for the starting observation at each period. The measure is based on the influence of effects on simulated micro-steps and takes the complete model specification into account. Therefore, required arguments are the analysed data given as a `siena` data object (necessary for the micro-steps simulations) as well as the complete model specification represented either by an estimated `sienaFit` object or by the triple consisting of a suitable parameter vector `theta` and the corresponding `sienaAlgorithm` and `sienaEffects` objects.

Usage

```
  interpret_size_dynamics(data, ans=NULL, theta=NULL,
     algorithm=NULL, effects=NULL, depvar=NULL,
     intervalsPerPeriod=NULL, n3 = NULL, useChangeContributions=FALSE,
     silent=TRUE, seed=NULL)
  ## S3 method for class 'sienaRIDynamics'
plot(x, staticRI=NULL, col=NULL,
     ylim=NULL, width=NULL, height=NULL, legend=TRUE,
     legendColumns=NULL, legendHeight=NULL, cex.legend=NULL, ...)
```

Arguments

`data`	`siena` data object representing the analyzed data and resulting from a call to `sienaDataCreate`.

ans — sienaFit object resulting from a call to siena07. The sienaFit object contains all necessary information on the model specification, in particular, the vector of parameter values ans$theta, the used algorithm for estimation ans$x, and information on included model effects ans$effects. If ans is a valid sienaFit object, the calculations of relative importances are based on ans$theta, ans$x, and ans$effects. Alternatively, the necessary information can be given directly as a suitable parameter vector theta, a sienaAlgorithm object, and a sienaEffects object. In this case, ans has to be unspecified (i.e., ans=NULL).

theta — Vector of parameter values of effects included in the model. Length of theta has to be equal to the number of included effects (rate effects as well as evaluation effects).

algorithm — sienaAlgorithm object as resulting from a call to sienaAlgorithmCreate. Works only for estimation by Method of Moments (i.e., if maxlike = FALSE).

effects — sienaEffects object specifying which effects are included the model.

depvar — If the model contains more than one dependent variable, it has to be specified for which dependent variable the relative importances of associated effects should be determined. Only those simulated ministeps that refer to the selected dependent variable are considered in the aggregated values of relative importance of the corresponding effects. If depvar=NULL, relative importances will be determined for the first element in the list of dependent variables of data (attr(data$depvars,"names")[1]).

intervalsPerPeriod — For analyzing the dynamics of relative importances between observation moments, the time interval between observation moments is divided into intervalsPerPeriod subintervals. The values of relative importance are aggregated over all ministeps of one subinterval. Default value is 10 subintervals per period.

n3 — Integer specifying the number of chains to be simulated. Defaults to the value in algorithm or what was set when estimating ans. A very large value will result in a long computation time and large memory usage.

silent — Logical specifying whether output during internal siena calls should be suppressed. Default is TRUE.

seed — Integer specifying the seed for random number generation during internal siena calls.

useChangeContributions — Logical specifying whether previously extracted change contributions should be used instead of rerunning phase 3 simulations.

x — interpret_size_dynamics object resulting from a call to interpret_size_dynamics.

staticRI — sienaRI object corresponding to the same model and data as x. If staticRI is specified, the expected relative importances of effects at observation moment are indicated in the plot by circlets at the beginning of each period.

col — Colors used in the plot. If col=NULL a default color scheme is used.

ylim — A vector of two numbers specifying the maximum and minimum value of the y-range visible in the plot. If ylim=NULL default values are used.

width	Width of the plot. If width=NULL a default value is used.
height	Height of the plot. If height=NULL a default value is used.
legend	Boolean: if TRUE a legend is added to the plot. x$effectNames are used as labels.
legendColumns	Number of columns in legend. If legendColumns=NULL a default value is used. Only effective if legend=TRUE.
legendHeight	Height of legend. If legendHeight=NULL a default value is used. Only effective if legend=TRUE.
cex.legend	Specifies the relative font size of legend labels.
...	Other arguments.

Details

interpret_size_dynamics takes the data as well as the complete model specification into account. Therefore, necessary arguments are the analyzed data given as a siena data object as well as the complete model specification represented either by an estimated sienaFit object or by the triple consisting of a suitable parameter vector theta and the corresponding sienaAlgorithm and sienaEffects objects.

Note that interpret_size_dynamics works only with Method of Moments
(i.e., for sienaAlgorithm objects with maxlike = FALSE).

If ans is a valid sienaFit object that resulted from a call to siena07 with unconditional estimation (i.e., for sienaAlgorithm objects with cond = FALSE), the calculations of relative importances are based on ans$theta, ans$x, and ans$effects. (Note that if the estimation of ans has been conditional on a dependent variable, it is necessary to give the associated sienaEffects object explicitly to interpret_size_dynamics).

Alternatively, the necessary information can be given directly as a suitable parameter vector theta (containing necessary rate and evaluation parameters), a sienaAlgorithm object,
and a sienaEffects object. In this case, ans has to be unspecified, i.e., ans=NULL.

If the sienaFit object ans was already estimated with returnChangeContributions=TRUE, the change contributions are stored in ans$changeContributions and can be used to estimate the relative importances of effects in interpret_size_dynamics without running any additional simulations. In this case, useChangeContributions has to be set to TRUE and n3 is ignored, since the number of chains is determined by the previous siena07 run. If useChangeContributions=FALSE, new chains are simulated internally with siena07 and the change contributions are calculated from these chains. The number of simulations is determined by the value of n3 or the value of algorithm$n3 if algorithm is specified. Otherwise, it defaults to the value of ans$n3 if ans is specified.

Value

interpret_size_dynamics returns an object of class sienaRIDynamics.

A returned interpret_size_dynamics object stores the relative importances of effects in simulated mini-steps aggregated to intervalsPerPeriod averages per period. For details, see Section 3.2 of Indlekofer and Brandes (2013).

A interpret_size_dynamics object consists of following components:

`intervalValues` the relative importances of included effects for simulated ministeps of the considered dependent variable aggregated over subintervals.

`dependentVariable` the name of the dependent variable the results refer to.

`effectNames` the names of considered effects.

`iwlsm` *Function to fit an iterated weighted least squares model.*

Description

Fits an iterated weighted least squares model.

Usage

```
iwlsm(x, ...)

## S3 method for class 'formula'
iwlsm(formula, data, weights, ses, ..., subset, na.action,
    method = c("M", "MM", "model.frame"),
    wt.method = c("inv.var", "case"),
    model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
iwlsm(x, y, weights, ses, ..., w = rep(1/nrow(x), nrow(x)),
    init = "ls", psi = psi.iwlsm,
    scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
    method = c("M", "MM"), wt.method = c("inv.var", "case"),
    maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.iwlsm(u, k, deriv = 0, w, sj2, hh)
```

Arguments

formula	a formula of the form y ~ x1 + x2 + ...
data	data frame from which variables specified in formula are preferentially to be taken.
weights	a vector of prior weights for each case.
subset	An index vector specifying the cases to be used in fitting.
ses	Estimated variance of the responses. Will be passed to psi as sj2
na.action	A function to specify the action to be taken if NAs are found. The 'factory-fresh' default action in R is na.omit, and can be changed by options(na.action=).
x	a matrix or data frame containing the explanatory variables.
y	the response: a vector of length the number of rows of x.
method	Must be "M". (argument not used here).
wt.method	are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable? This will not work at present.
model	should the model frame be returned in the object?
x.ret	should the model matrix be returned in the object?
y.ret	should the response be returned in the object?
contrasts	optional contrast specifications: se lm.
w	(optional) initial down-weighting for each case. Will not work at present.
init	(optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a coef component. Known methods are "ls" (the default) for an initial least-squares fit using weights w*weights, and "lts" for an unweighted least-trimmed squares fit with 200 samples. Probably not functioning.
psi	the psi function is specified by this argument. It must give (possibly by name) a function g(x, ..., deriv, w) that for deriv=0 returns psi(x)/x and for deriv=1 returns some value. Extra arguments may be passed in via ....
scale.est	method of scale estimation: re-scaled MAD of the residuals (default) or Huber"s proposal 2 (which can be selected by either "Huber" or "proposal 2").
k2	tuning constant used for Huber proposal 2 scale estimation.
maxit	the limit on the number of IWLS iterations.
acc	the accuracy for the stopping criterion.
test.vec	the stopping criterion is based on changes in this vector.
...	additional arguments to be passed to iwlsm.default or to the psi function.
lqs.control	An optional list of control values for lqs.
u	numeric vector of evaluation points.
k	tuning constant. Not used.
deriv	0 or 1: compute values of the psi function or of its first derivative. (Latter not used).
sj2	Estimated variance of the responses
hh	Diagonal values of the hat matrix

Details

This function is very slightly adapted from rlm in packages MASS. It alternates between weighted least squares and estimation of variance on the basis of a common variance. The function psi.iwlsm calculates the weights for the next iteration. Used by meta_siena to combine estimates from different sienaFits.

Value

An object of class "iwlsm" inheriting from "lm". Note that the df.residual component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.

The additional components not in an lm object are

s	the robust scale estimate used
w	the weights used in the IWLS process
psi	the psi function with parameters substituted
conv	the convergence criteria at each iteration
converged	did the IWLS converge?
wresid	a working residual, weighted for "inv.var" weights only.

Note

The function has been changed as little as possible, but has only been used with default arguments. The other options have been retained just in case they may prove useful.

`make_constraint` *Function to change the values of the constraints between networks*

Description

This function allows the user to change the constraints of "higher", "disjoint" and "atLeastOne" for a specified pair of networks in a Siena data object.
The functions `make_constraint` and `sienaDataConstraint` are identical. The first name is preferred, the other is kept for backward compatibility.
The functions `make_constraint` and `sienaDataConstraint` are identical. The first name is preferred, the other is kept for backward compatibility.

Usage

```
## S3 method for class 'sienadata'
make_constraint(x, net1, net2, type, value = FALSE, ...)
## S3 method for class 'sienaGroup'
make_constraint(x, net1, net2, type, value = FALSE, ...)

sienaDataConstraint(x, net1, net2, type, value = FALSE)
```

Arguments

`x`	`sienadata` object or a `sienaGroup` object
`net1`	name of first network
`net2`	name of second network
`type`	one of "higher", "disjoint", "atleastOne".
`value`	Boolean giving the value.
`...`	Additional arguments, not used now.

Details

The value of the appropriate attribute is set to the value requested. Note that, for `value=TRUE`, the correspondence of this value to the data is not checked.

Value

Updated `sienadata` object.

make_data_rsiena *Function to create a Siena data object*

Description

Creates a Siena data object from input dependent variables (networks and possibly behavioural variables), covariates, and composition change objects.
The functions `make_data_rsiena` and `sienaDataCreate` are identical. The first name is preferred, the other is kept for backward compatibility.

Usage

```
make_data_rsiena(..., nodeSets=NULL)

sienaDataCreate(..., nodeSets=NULL, getDocumentation=FALSE)
```

Arguments

...	objects of class sienaDependent, coCovar, varCovar, coDyadCovar, varDyadCovar, and/or sienaCompositionChange; or a list of such objects, of which the first element must not be a sienaCompositionChange object. There should be at least one sienaDependent object. If there are one-mode as well as two-mode dependent networks, the one-mode networks should be mentioned first.
nodeSets	list of Siena node sets. Default is the single node set named Actors, length equal to the number of rows in the first object of class sienaDependent. If the entire data set contains more than one node set, then the node sets must have been specified in the creation of all data objects mentioned in ....
getDocumentation	Flag to allow documentation of internal functions, not for use by users.

Details

The function checks that the objects fit, that there is at least one dependent variable, and adds various attributes to each variable describing the data. If there is more than one nodeSet they must all be specified.
Function print01Report will give a basic description of the data object and is a check useful, e.g., for diagnosing problems.

Value

An object of class sienadata which is designed to be used in a siena model fit by siena.
In RSiena versions prior to 1.6, the class name was siena.
The components of the object are:

nodeSets	List of node sets involved
observations	Integer indicating number of waves of data
depvars	List of networks and behavior variables
cCovars	List of constant covariates
vCovars	List of changing covariates
dycCovars	List of constant dyadic covariates
dyvCovars	List of changing dyadic covariates
compositionChange	List of composition change objects corresponding to the node sets

make_group_rsiena *Function to group together several Siena data objects*

Description

Creates an object of class "sienaGroup" from a list of Siena data objects.
The functions make_group_rsiena and sienaGroupCreate are identical. The first name is preferred, the other is kept for backward compatibility.

Usage

```
make_group_rsiena(objlist, singleOK = FALSE)

sienaGroupCreate(objlist, singleOK = FALSE, getDocumentation=FALSE)
```

Arguments

objlist	List of objects of class siena.
singleOK	Boolean: is it OK to only have one object?
getDocumentation	Flag to allow documentation of internal functions, not for use by users.

Details

This function creates a Siena group object from several Siena data objects ('groups'), all of which use networks, covariates and actor sets with the same names. The variables must correspond exactly between all data objects; the numbers of waves may differ. It can be used as data input to siena07 for the multigroup option. Also used internally for convenience with a single Siena data object.

Each covariate should either be centered in all groups, or non-centered in all groups. Centered actor covariates are re-centered at the overall mean. This means that the original values are used, and the overall mean of all non-missing observations is subtracted. Note that this implies that group-dependent variables that are constant for all actors in each group, can be used as centered actor covariates.

For combining two-wave with more-wave groups in one group object, covariates that are changing covariates for the more-wave groups have to be specified as changing covariates also for the two-wave groups. This can be done by specifying them with values for the two waves; for actor covariates this will be by using an $n \times 2$ matrix, for dyadic covariates an $n \times n \times 2$ array (or $n \times m \times 2$ for the two-mode case). The values for the second wave should be identical to those for the first wave (they will be used only for centering operations).

For later use in siena, it will often (but not always...) be helpful when creating the Siena data objects in objlist to use allowOnly=FALSE in the call of as_dependent_rsiena; see the help page for this function.

If there are multiple dependent networks, it may be necessary to run make_constraint.sienadata before make_group_rsiena to ensure that these constraints are equal for all groups.

Value

An object of class sienaGroup; this is a list containing the input objects, with attributes:

netnames	names of the dependent variables in each set
symmetric	vector of booleans, one for each dependent variable. TRUE if all occurrences of the network are symmetric.
structural	vector of booleans, indicating whether structurally fixed values occur in this network
allUpOnly	vector of booleans, indicating whether changes are all upwards in all the occurrences of this network
allDownOnly	similar to previous, but for downward changes
anyUpOnly	vector of booleans, indicating whether changes are all upwards in any of the occurrences of this network
anyDownOnly	similar to previous, but for downward changes

types	vector of network types of the dependent variables
observations	Total number of periods to process
periodNos	Sequence of numbers of periods which are not skipped in multigroup processing
netnodeSets	list of names of the node sets corresponding to the dependent variables
cCovars	names of the constant covariates, if any
vCovars	names of the changing covariates, if any
dycCovars	names of the constant dyadic covariates, if any
dyvCovars	names of the changing dyadic covariates, if any
ccnodeSets	list of the names of the node sets corresponding to the constant covariates
cvnodeSets	list of the names of the node sets corresponding to the changing covariates
dycnodeSets	list of the names of the node sets corresponding to the constant dyadic covariates
dyvcnodeSets	list of the names of the node sets corresponding to the changing dyadic covariates
compositionChange	boolean: any composition change at all?
exooptions	named vector of composition change options for the node sets
names	Either from the input objects or "Data1", "Data2" etc
class	"sienaGroup" inheriting from "siena"
balmean	vector of means for balance calculations
bRange	vector of difference between maximum and minimum values for behavior variables, NA for other dependent variables
behRange	matrix of maximum and minimum values for behavior variables, NA for other dependent variables
bSim	vector of similarity means for behavior variables, NA for other dependent variables
bPoszvar	vector of booleans indicating positive variance for behavior variables. NA for other dependent variables
bMoreThan2	vector of booleans indicating whether the behavior variables take more than 2 distinct values
cCovarPoszvar	vector of booleans indicating positive variance for constant covariates
cCovarMoreThan2	vector of booleans indicating whether the constant covariates take more than 2 distinct values
cCovarRange	vector of difference between maximum and minimum values for constant covariates
cCovarRange2	matrix of maximum and minimum values for constant covariates
cCovarSim	vector of similarity means for constant covariates
cCovarMean	vector of means for constant covariates
vCovarRange	vector of difference between maximum and minimum values for changing covariates

vCovarSim	vector of similarity means for changing covariates
vCovarMoreThan2	vector of booleans indicating whether the changing covariates take more than 2 distinct values
vCovarPoszvar	vector of booleans indicating positive variance for changing covariates
vCovarMean	vector of means for changing covariates
dycCovarMean	vector of means for constant dyadic covariates
dycCovarRange	vector of ranges for constant dyadic covariates
dycCovarRange2	matrix of maximum and minimum values for constant dyadic covariates
dyvCovarRange	vector of ranges for changing dyadic covariates
dyvCovarMean	vector of means for changing dyadic covariates
anyMissing	vector of booleans, one for each dependent variable, indicating the presence of any missing values
netRanges	matrix of maximum and minimum values for dependent networks, NA for behavior variables

dataset.6 <- make_data_rsiena(Friends = Group6, dum1 = dum1.6)
(FourGroups <- make_group_rsiena(list(dataset.1, dataset.3, dataset.4,
```

```
                                        dataset.6)))
class(FourGroups)
# The main effect of the group-level variable is the \code{egoX} effect:
myeff <- make_specification(FourGroups)
(myeff <- set_effect(myeff, egoX, covar1 = "dum1"))
```

`make_specification` *Function to create a Siena effects object*

Description

Creates a basic list of effects for all dependent variables in the input siena object.
The functions `make_specification` and `getEffects` are identical.
The first name is preferred, the other is kept for backward compatibility.

Usage

```
## S3 method for class 'sienadata'
make_specification(x, nintn = 10, behNintn=4, onePeriodSde=FALSE, ...)

## S3 method for class 'sienaGroup'
make_specification(x, nintn = 10, behNintn=4, onePeriodSde=FALSE, ...)

getEffects(x, nintn = 10, behNintn=4, getDocumentation=FALSE,
           onePeriodSde=FALSE)
```

Arguments

`x`	an object of class "sienadata" or "sienaGroup"
`nintn`	Number of user-defined network interactions that can later be created.
`behNintn`	Number of user-defined behavior interactions that can later be created.
`onePeriodSde`	Flag to indicate that the stochastic differential equation (SDE) model dZ(t) = [aZ(t) + b] dt + g dW(t) should be used, instead of the regular SDE with a scale parameter. This is only relevant in case the model includes a continuous dependent variable and one period is studied.
`getDocumentation`	Flag to allow documentation of internal functions, not for use by users.
`...`	Additional arguments, not used now.

Details

Creates a data frame of effects for use in siena model estimation. The regular way of changing this object is by the functions `includeEffects`, `setEffect`, and `includeInteraction`.

Note that the class of the return object may be lost if the data.frame is edited using `fix`. See `fix` and `edit.data.frame`.

Value

An object of class `sienaEffects` or `sienaGroupEffects`: this is a data frame of which the rows are the effects available for data set `x`.
The effects object consists of consecutive parts, each of which relates to one dependent variable in the input object. The columns are:

`name`	name of the dependent variable
`effectName`	name of the effect
`functionName`	name of the function
`shortName`	short name for the effect
`interaction1`	second variable to define the effect, if any
`interaction2`	third variable to define the effect, if any
`type`	"eval", "endow", "creation", "rate", or "gmm"
`basicRate`	boolean: whether a basic rate parameter
`include`	boolean: include in the model to be fitted or not
`randomEffects`	boolean: random or fixed effect. Currently not used.
`fix`	boolean: fix parameter value or not
`test`	boolean: test parameter value or not
`timeDummy`	comma separated list of periods, or "all", or "," for none – which time dummy interacted parameters should be included?
`initialValue`	starting value for estimation, also used for `fix` and `test`.
`parm`	internal effect parameter values
`functionType`	"objective" or "rate"
`period`	period for basic rate parameters
`rateType`	"Structural", "covariate", "diffusion"
`untrimmedValue`	Used to store initial values which could be trimmed
`effect1`	Used to indicate effect number in user-specified interactions
`effect2`	Used to indicate effect number in user-specified interactions
`effect3`	Used to indicate effect number in user-specified interactions
`interactionType`	Defines "dyadic" or "ego" or "OK" effects, used in `includeInteraction`
`local`	whether a local effect; used for the option `localML` in `set_algorithm_saom`
`effectFn`	here NULL, but could be replaced by a function later
`statisticFn`	here NULL, but could be replaced by a function later
`netType`	Type of dependent variable: "oneMode", "behavior", or "bipartite"
`groupName`	name of relevant group data object
`group`	sequential number of relevant group data object in total
`effectNumber`	the sequence number of the row

The combination of name, shortName, interaction1, interaction2, and type uniquely identifies any effect other than basic rate effects and user-specified interaction effects. For the latter, effect1, effect2 and effect3 are also required for the identification. The combination name, shortName, period and group uniquely identifies a basic rate effect.

The columns not used for identifying the effect define how the effect is used for the estimation.

The columns initialValue and parm should not be confused: initialValue gives the initial value for the parameter to be estimated, indicated in the manual by theta; parm gives the internal value of the parameter defining the effect, indicated in the manual (Chapter 12) by p, and is fixed during the estimation.

Note that if an effects object is printed by print(...), by default only the included rows are printed.

A list of all effects in a given effects object (e.g., myeff), including their names of dependent variables, effect names, short names, and values of interaction1 and interaction2 (if any), is obtained by executing effectsDocumentation(myeff).

As from version 1.3.24, effects object have a "version" attribute. Effects objects including interaction effects created by set_interaction are not necessarily compatible between versions of RSiena. Therefore it is recommended, for effects objects including any interaction effects, to create them again when changing to a new version of RSiena. If an effects object including any interaction effects is used from an old version of RSiena, this will lead to a warning when running siena.

myeff
```

meta_siena *Function to perform a meta analysis of a collection of Siena fits.*

Description

Estimates a meta analysis based on a collection of Siena fits.
`meta_siena()` and `siena08()` are identical functions, differing only in the keyword for the output file. The first name is preferred, the other is kept for backward compatibility.

Usage

```
meta_siena(..., outputName = "sienaMeta", bound = 10, alpha = 0.05, maxit=20)

siena08(..., projname = "sienaMeta", bound = 10, alpha = 0.05, maxit=20)
```

Arguments

`...`	names of `sienaFit` objects, returned from `siena`. They will be renamed if entered in format `newname=oldname`. It is also allowed to give for ... a list of `sienaFit` objects.
`outputName`	Base name of report file if required.
`projname`	Base name of report file if required.
`bound`	Upper limit of standard error for inclusion in the meta analysis.
`alpha`	1 minus confidence level of confidence intervals.
`maxit`	Number of iterations of iterated least squares procedure.

Details

A meta analysis is performed as described in the Siena manual, section "Meta-analysis of Siena results". This consists of three parts: an iterated weighted least squares (IWLS) modification of the method described in the reference below; maximum likelihood estimates and confidence intervals based on profile likelihoods under normality assumptions; and Fisher combinations of left-sided and right-sided p-values. These are produced for all effects separately.

Note that the corresponding effects must have the same effect name in each model fit. This implies that at least covariates and behavior variables must have the same name in each model fit.

Value

An object of class `sienaMeta`. There are `print`, `summary` and `plot` methods for this class. This object contains at least the following.

`thetadf`	Data frame containing the coefficients, standard errors and score test results
`projname`	Root name for any output file to be produced by the print method
`bound`	Estimates with standard error above this value were excluded from the calculations

scores	Object of class by indicating, for each effect in the models, whether score test information was present.
requestedEffects	The requestedEffects component of the first sienaFit object in ....
muhat	The vector of IWLS estimates.
se.muhat	The vector of standard errors of the IWLS estimates.
theta	The vector of ML estimates mu.ml (see below).
se	The vector of standard errors of the ML estimates mu.ml.se (see below).

Then for each effect, there is a list with at least the following.

cor.est	Spearman rank correlation coefficient between estimates and their standard errors.
cor.pval	p-value for above
regfit	Part of the result of the fit of iwlsm.
regsummary	The summary of the fit, which includes the coefficient table.
Tsq	test statistic for effect zero in every model
pTsq	p-value for above
tratio	test statistics that mean effect is 0
ptratio	p-value for above
Qstat	Test statistic for variance of effects is zero
pttilde	p-value for above
cjplus	Test statistic for at least one theta strictly greater than 0
cjminus	Test statistic for at least one theta strictly less than 0
cjplusp	p-value for cjplus
cjminusp	p-value for cjminus
mu.ml	ML estimate of population mean
mu.ml.se	standard error of ML estimate of population mean
sigma.ml	ML estimate of population standard deviation
mu.confint	confidence interval for population mean based on profile likelihood
sigma.confint	confidence interval for population standard deviation based on profile likelihood
n1	Number of fits on which the meta analysis is based
cjplus	Test statistic for combination of right one-sided Fisher combination tests
cjminus	Test statistic for combination of left one-sided Fisher combination tests
cjplusp	p-value for cjplus
cjminusp	p-value for cjminus
scoreplus	Test statistic for combination of right one-sided p-values from score tests
scoreminus	Test statistic for combination of left one-sided p-values from score tests
scoreplusp	p-value for scoreplus
scoreminusp	p-value for scoreminus
ns	Number of fits on which the score test analysis is based

n3401 *Network data: excerpt from "Dutch Social Behavior Data Set" of Chris Baerveldt.*

Description

Matrices N3401, N3403, N3404, N3406, and HN3401, HN3403, HN3404, HN3406 are two waves of networks for four schools (numbered 1, 3, 4, 6).

Format

Adjacency matrices for the network at two time points. The matrices with name N... are the first wave, those with name HN... are the second wave.

There is a tie from pupil i to pupil j if i says that he/she receives and/or gives emotional support from/to pupil j. The data are part of a larger data set (see source below) and were collected under the direction of Chris Baerveldt.

```

`plot.sienaTimeTest` *Functions to plot assessment of time heterogeneity of parameters*

Description

Plot method for `sienaTimeTest` objects.

Usage

```
## S3 method for class 'sienaTimeTest'
plot(x, pairwise=FALSE, effects,
     scale=.2, plevels=c(.1, .05, .025), ...)
```

Arguments

`x`	A sienaTimeTest object returned by `test_time`.
`pairwise`	A Boolean value corresponding to whether the user would like a pairwise plot of the simulated statistics to assess correlation among the effects (`pairwise=TRUE`), or a plot of the estimates across waves in order to assess graphically the results of the score type test.
`effects`	A vector of integers corresponding to the indices given in the `sienaTimeTest` output for effects which are to be plotted.
`scale`	A positive number corresponding to the number of standard deviations on one step estimates to use for computing the maximum and minimum of the plotting range. We recommend experimenting with this number when the y-axes of the plots are not satisfactory. Smaller numbers shrink the axes.
`plevels`	A list of three decimals indicating the gradients at which to draw the confidence interval bars.
`...`	For extra arguments. The Lattice parameter `layout` can be used to control the layout of the graphs.

Details

The `pairwise=TRUE` plot may be used to assess whether effects are highly correlated. This information may be important when considering forward-model selection, since highly correlated effects may have highly correlated one-step estimates, particularly since the individual score type tests are not orthogonalized against the scores and deviations of yet-unestimated dummies. For example, reciprocity and outdegree may have highly correlated statistics as indicated by a strong, positive correlation coefficient. When considering whether to include dummy terms, it may be a good idea to include, e.g., outdegree, estimate the parameter, and see whether reciprocity dummies remain significant after method of moments estimation of the updated model–as opposed to including both outdegree and reciprocity.

The `pairwise=FALSE` plot displays the most of the information garnered from `sienaTimeTest` in a graphical fashion. For each effect, the method of moments parameter estimate for the base period (i.e. wave 1) is given as a blue, horizontal reference line. One step estimates are given for all of

the parameters by dots at each wave. The dots are colored black if the parameter has been included in the model already (i.e. has been estimated via method of moments), or red if they have not been included. Confidence intervals are given based on pivots given at `pvalues`. Evidence of time heterogeneity is suggested by points with confidence intervals not overlapping with the base period.

Value

None

myalgo <- set_algorithm_saom(nsub=2, n3=200)
# It makes no sense to put together the following data set,
# but just for demonstration:
mynet1 <- as_dependent_rsiena(
          array(c(s501, s502, s503, s501, s503, s502), dim=c(50, 50, 6)))
mydata <- make_data_rsiena(mynet1)
myeff <- make_specification(mydata)
myeff <- set_effect(myeff, transTrip)
myeff <- includeTimeDummy(myeff, density, timeDummy="all")
myeff <- includeTimeDummy(myeff, recip, timeDummy="2,3,5")
myeff <- includeTimeDummy(myeff, transTrip, timeDummy="2,3")
(ansp <- siena(mydata, effects=myeff, batch=TRUE, control_algo=myalgo))
ttp <- test_time(ansp)
summary(ttp)

## Pairwise plots show
plot(ttp, pairwise=TRUE)

## Time test plots show
plot(ttp, effects=1:3) ## default layout
plot(ttp, effects=1:3, layout=c(3,1))

## End(Not run)
```

`print.sienaEffects` *Print methods for Siena effects objects*

Description

Prints the major columns of the effects object. Or all, with any non-atomic columns listed separately.

Usage

```
## S3 method for class 'sienaEffects'
print(x, fileName = NULL, includeOnly=TRUE,
   expandDummies = FALSE, includeRandoms = FALSE, dropRates=FALSE,
   includeShortNames=FALSE, ...)
## S3 method for class 'sienaEffects'
summary(object, fileName = NULL,
   includeOnly=TRUE, expandDummies = FALSE, ...)
## S3 method for class 'summary.sienaEffects'
print(x, fileName = NULL, ...)
```

Arguments

`object`	An object of class `sienaEffects`.
`x`	An object of class `sienaEffects` or `summary.sienaEffects` as appropriate.
`fileName`	Character string denoting file name if file output desired.
`includeOnly`	Boolean. If `TRUE`, only effects with the include flag `TRUE` will be printed.
`expandDummies`	Interpret the `timeDummy` column and show any effects which would be added by `sienaTimeFix`.
`includeRandoms`	Boolean. If `TRUE`, also the `randomEffects` column will be printed.
`includeShortNames`	Boolean. If `TRUE`, also the `shortName` column will be printed.
`dropRates`	Boolean. If `TRUE`, do not print the rows for basic rate effects.
`...`	For extra arguments (none used at present).

Value

The function `print.sienaEffects` prints details of the main columns of the selected rows of the effects object.
If the effects object includes statistics for the Generalized Method of Moments (GMoM), as included by function `includeGMoMStatistics` and for which `type=gmm`, the print consists of two parts: the first consists of the included effects for the probability model, the second of the statistics used for GMoM estimation.

The function `summary.sienaEffects` checks the rows for valid printing via `print.data.frame` and excludes any that will fail. The OK columns are printed first, followed by any others.

Output from either can be directed to a file by using the argument `filename`.

print.sienaMeta *Methods for processing sienaMeta objects*

Description

print, summary, and plot methods for sienaMeta objects; and a function to write a LaTeX table.

Usage

```
## S3 method for class 'sienaMeta'
print(x, file=FALSE, reportEstimates=FALSE, ...)

## S3 method for class 'sienaMeta'
summary(object, file=FALSE, extra=TRUE, ...)

## S3 method for class 'summary.sienaMeta'
print(x, file=FALSE, extra=TRUE, ...)

## S3 method for class 'sienaMeta'
plot(x, ..., which = 1:length(x$theta),
                          useBound=TRUE, layout = c(2,2))
meta.table(x, d=3, option=2,
    filename=paste(deparse(substitute(x)),'_global.tex',sep=""), align=TRUE)
```

Arguments

object	An object of class sienaMeta.
x	An object of class sienaMeta, or summary.sienaMeta as appropriate.
file	Boolean: if TRUE, sends output to file named x$projname.txt. If FALSE, output is to the terminal.
reportEstimates	Boolean: whether to report all estimates and standard errors.
extra	Boolean: if TRUE, prints more information.
which	Set of effects contained in the plot (given by sequence numbers).
useBound	Boolean: whether to restict plotted symbols to the bound used in the call of sienaMeta.
layout	Vector giving number of rows and columns in the arrangement of the several panels in a rectangular array, possibly spanning multiple pages.
d	Number of decimals to be used in table.
option	1: results without normality assumptions; 2: results with normality assumptions, with confidence intervals; 3: results with normality assumptions, with standard errors.
filename	filename for output; if "", printed to the console.
align	Whether to align numbers at the decimal point.
...	For extra arguments (none used at present).

Value

The function print.sienaMeta prints details of the merged estimates of the meta-analysis carried out by meta_siena, with test statistics. See the help page for meta_siena for what is produced by this function.

The function summary.sienaMeta prints details as for the print method, but also details of the sienaFit objects included.

Output from either can be directed to a file by using the argument file. It will be appended to any existing file of the same name: outputName.txt where outputName is the value of the argument to meta_siena.

The function meta.table writes a combined table of results for all parameters to a LaTeX file in (as default) the current working directory. This table is a more compact version of the results presented by print.sienaMeta.

The function plot.sienaMeta plots estimates against standard errors for each effect, with reference lines added at the two-sided significance threshold 0.05. It returns an object of class trellis, of the **lattice** package. Effects for which a score test was requested are not plotted.
Another funnel plot, not using meta_siena, is available as funnelPlot.

`print.sienaTest` *Print method for Wald and score tests for RSiena results*

Description

This method prints Wald-type and score-type tests for results estimated by `siena`.

Usage

```
## S3 method for class 'sienaTest'
print(x, ...)
```

Arguments

`x`	An object of type `sienaTest`, produced by `test_parameter`.
`...`	Extra arguments (not used at present).

Details

The function `test_parameter` produces an object of type `sienaTest`. These can be printed by this method.

Value

An object of type `sienaTest`.

s50

Network data: excerpt from "Teenage Friends and Lifestyle Study" data.

Description

An excerpt of the network, alcohol consumption, and smoking data for 50 randomly chosen girls from the Teenage Friends and Lifestyle Study data set. Useful as a small example of network and behaviour, for which models can be fitted quickly, and for which there are no missing values.

Format

Adjacency matrix for the network at time points 1, 2, 3; 50 by 3 matrices of alcohol consumption and smoking data for the three time points.

set_algorithm *Functions to create objects containing various aspects of algorithm specifications for parameter estimation in RSiena*

Description

Create objects containing various aspects of algorithm specifications for parameter estimation in RSiena.
`set_model_saom` sets the specifications of the Stochastic Actor-oriented Model.
`set_algorithm_saom` sets the specifications of the algorithm for parameter estimation of the model.
`set_output_saom` sets the specifications of the generated output.

These three aspects are combined in the older functions `sienaAlgorithmCreate` and `sienaModelCreate`, which are identical functions although having different names. The older functions are not preferred any more, but are kept for backward compatibility.

Usage

```
  set_model_saom(modelType = NULL, behModelType = NULL,
                       MaxDegree = NULL, Offset = NULL)

  set_algorithm_saom(maxlike = FALSE, gmm = FALSE,
    cond = NA, condvarno = 0, condname = "",
    simOnly = FALSE,
    targets = NULL, thetaValues = NULL, seed = NULL,
    n3 = 1000, nsub = 4, n2start = NULL, firstg = 0.2, reduceg = 0.5,
    truncation = 5, doubleAveraging = 0,
    diagonalize = 0.2*!maxlike, standardizeVar = (diagonalize<1),
    dolby = TRUE, splitDepvars = 0,
useStdInits = FALSE, findiff = FALSE,
    mult = 5, prML = 1, maximumPermutationLength = 40,
    minimumPermutationLength = 2, initialPermutationLength = 20,
    localML = FALSE)

set_output_saom(outputName = NULL, lessMem = FALSE,
    returnThetas = FALSE,
    returnChains = FALSE, returnDataFrame = FALSE,
    returnChangeContributions = FALSE)

sienaAlgorithmCreate(fn, projname = "Siena", MaxDegree = NULL,
     Offset = NULL, useStdInits = FALSE,
     n3 = 1000, nsub = 4, n2start = NULL,
     dolby = TRUE, splitDepvars = 0,
 maxlike = FALSE, gmm = FALSE,
     diagonalize = 0.2*!maxlike,
     condvarno = 0, condname = "", firstg = 0.2, reduceg = 0.5,
     cond = NA, findiff = FALSE, seed = NULL,
     prML = 1, maximumPermutationLength = 40,
     minimumPermutationLength = 2, initialPermutationLength = 20,
     modelType = NULL, behModelType = NULL, mult = 5, simOnly = FALSE,
     localML = FALSE, truncation = 5, doubleAveraging = 0,
     standardizeVar = (diagonalize<1), lessMem = FALSE, silent = FALSE)

sienaModelCreate(fn, projname = "Siena", MaxDegree = NULL,
     Offset = NULL, useStdInits = FALSE,
     n3 = 1000, nsub = 4, n2start = NULL,
     dolby = TRUE,  splitDepvars = 0,
 maxlike = FALSE, gmm = FALSE,
     diagonalize = 0.2*!maxlike,
     condvarno = 0, condname = "", firstg = 0.2, reduceg = 0.5,
     cond = NA, findiff = FALSE, seed = NULL,
     prML = 1, maximumPermutationLength = 40,
     minimumPermutationLength = 2, initialPermutationLength = 20,
     modelType = NULL, behModelType = NULL, mult = 5, simOnly = FALSE,
     localML = FALSE, truncation = 5, doubleAveraging = 0,
```

```
standardizeVar = (diagonalize<1), lessMem = FALSE, silent = FALSE)
```

Arguments

For `set_model_saom`:

`modelType`	Named vector indicating the type of model to be fitted for dependent network variables. (See the examples below for how to specify a named vector.) Possible values are: 1 = directed standard, 2:6 for symmetric networks only: 2 = dictatorial forcing (D.1), 3 = Initiative model with reciprocal confirmation (M.1), 4 = Pairwise dictatorial forcing model (D.2), 5 = Pairwise mutual model (M.2), 6 = Pairwise joint model (C.2), 7:10 for directed one-mode only: 7 = Double Step model with double step probability 0.25, 8 = Double Step model with double step probability 0.50, 9 = Double Step model with double step probability 0.75, 10 = Double Step model with double step probability 1.00, 11 = Contemporaneous evaluation statistics model. Names should be the names of all dependent network variables, in the same order as in the Siena data set. See Snijders and Pickup (2016) for the meanings of the various models for symmetric networks. Default `NULL` implies 1 for directed or two-mode, 2 for symmetric.
`behModelType`	Named vector indicating the type of model to be fitted for behavioral dependent variables. (See the examples below for how to specify a named vector.) Possible values are: 1 = standard (restricted), 2 = absorbing. Names should be the names of all dependent behavioral variables, in the same order as in the Siena data set. Default `NULL` implies values 1.
`MaxDegree`	Named vector of maximum degree values for corresponding networks. Allows to restrict the model to networks with degrees not higher than this maximum. Names should be the names of all dependent network variables, in the same order as in the Siena data set. Default as well as value 0 imply no restrictions. This option is not available for maximum likelihood estimation.
`Offset`	Named vector of offset values for symmetric networks with `modelType = 3` (M.1), and for universal setting in Settings model. Names should be the names of all dependent network variables, in the same order as in the Siena data set. Default `NULL` implies values 0.

For `set_algorithm_saom`:

`maxlike`	Whether to use maximum likelihood method or Method of Moments estimation.
`gmm`	Whether to use the Generalized Method of Moments or the regular Method of Moments estimation.
`cond`	Boolean. Only relevant for Method of Moments simulation/estimation. If TRUE, use conditional simulation; if FALSE, unconditional simulation. If missing, de-

cision is deferred until siena, when it is set to TRUE if there is only one dependent variable, FALSE otherwise.

condvarno — If cond (conditional simulation), the sequential number of the network or behavior variable on which to condition.

condname — If conditional, the name of the dependent variable on which to condition. Use one or other of condname or condvarno to specify the variable.

simOnly — Logical: If TRUE, then the calculation of the covariance matrix and standard errors of the estimates at the end of Phase 3 of the estimation algorithm is skipped. This is suitable if nsub = 0 and siena is used only for the purpose of simulation.

targets — Numeric vector of length equal to the number of estimated parameters, meant to supersede the targets calculated from the data set; see "Details". Not for regular use.

thetaValues — If not NULL, this should be a matrix with parameter values to be used in Phase 3. The number of columns must be equal to the number of estimated parameters in the effects object (if conditional estimation is used, without the rate parameters for the conditioning dependent variable). Can only be used if simOnly=TRUE.

seed — Integer. Starting value of random seed.

n3 — Number of iterations in phase 3. For regular use with the Method of Moments, n3 = 1000 mostly suffices. For use in publications and for Maximum Likelihood, at least n3 = 3000 is advised. Sometimes much higher values are required for stable estimation of standard errors.

nsub — Number of subphases in phase 2.

n2start — Minimum number of iterations in subphase 1 of phase 2; default is 2.52*(p+7), where p = number of estimated parameters; if useCluster = TRUE in the call of siena07, this is divided by nbrNodes.

firstg — Initial value of scaling ("gain") parameter for updates in the Robbins-Monro procedure.

reduceg — Reduction factor for scaling ("gain") parameter for updates in the Robbins-Monro procedure (MoM only).

truncation — Used for step truncation in the Robbins Monro algorithm (applied to deviate/(standard deviation)).

doubleAveraging — subphase after which double averaging is used in the Robbins Monro algorithm, which probably increases algorithm efficiency.

diagonalize — Number between 0 and 1 (bounds included), values outside this interval will be truncated; for diagonalize = 0 the complete estimated derivative matrix will be used for updates in the Robbins-Monro procedure; for diagonalize = 1 only the diagonal entries will be used; for values between 0 and 1, the weighted average will be used with weight diagonalize for the diagonalized matrix. Has no effect for ML estimation.
Higher values are more stable, lower values potentially more efficient. Default: for ML estimation, diagonalize = 0; for MoM estimation, diagonalize = 0.2.

standardizeVar — Logical: whether to limit deviations used in Robbins-Monro updates to unit variances.

dolby — Boolean. Should there be noise reduction by regression on augmented data score. In most cases dolby = TRUE yields better convergence, but takes some extra computing time; if convergence is problematic, however, dolby = FALSE may be tried. Just use whatever works best.

splitDepvars — Integer with possible values -1, 0, +1. If -1, obtain results as in versions prior to 1.3.6. If +1, Robbins-Monro updates for a given dependent variable will not depend on deviations for other dependent variables. See Details.

useStdInits — Boolean. If TRUE, the initial values in the effects object will be ignored and default values used instead. If FALSE, the initial values in the effects object will be used.

findiff — Boolean: If TRUE, estimate derivatives using finite differences. If FALSE, use scores.

mult — Multiplication factor for maximum likelihood and Bayes. Number of steps per iteration is set to this multiple of the total distance between the observations at start and finish of the wave (and rounded). Decreasing mult below a certain value has no further effect.
mult can be either a number (which needs to be positive) or a vector of numbers, of length equal to the total number of periods. Note that for multi-group data, the total number of periods is equal to the number of groups times the number of periods per group (if the latter is constant).

Algorithm parameters only relevant for maximum likelihood and Bayesian estimation:

prML — Either one real number, or a vector of 7 numbers. Determines update probabilities used in Metropolis-Hastings routine in ML estimation. Should be nonnegative; if a vector, the sum should be < = 1. See Details.

maximumPermutationLength — Maximum length of permutation in steps in ML estimation.

minimumPermutationLength — Minimum length of permutation in steps in MLestimation.

initialPermutationLength — Initial length of permutation in steps in MLestimation.

localML — Logical: If TRUE, and maxlike, then calculations are sped up for models with all local effects.

For set_output_saom:

outputName — If outputName = NULL and the Siena data set has name dataName, output will be written by siena to a file with name dataName_out.txt in the working directory, appending if this file already exists.
If outputName is not NULL, it should be a character string without embedded spaces, and output will be written to a file with name outputName_out.txt.

lessMem — Logical: whether to reduce storage during operation of siena, and of the object produced, by leaving out arrays by iteration and by period of simulated statistics sf2 and scores ssc.
if lessMem = TRUE, it will be impossible to run test_time or test_gof on the object produced by siena.

`returnThetas` Boolean: whether to return theta values and generated estimation statistics of Phase 2 runs.

`returnChains` Boolean. Whether to return the chains generated in the Phase 3 runs.

`returnDataFrame`
Boolean. Whether to return the chains as lists or data frames.

`returnChangeContributions`
Boolean. Whether to return the change contributions. See `interpret_size_dynamics`.

And additional, for `sienaAlgorithmCreate`:

`fn` Function to do one simulation in the Robbins-Monro algorithm. Not to be touched.

`projname` Character string name of project; the output file will be called projname.txt. No embedded spaces!!!
If `projname = NULL`, output will be written to a file in the temporary session directory, created as `tempfile(Siena)`.

`silent` Logical: whether to give a note about the output file.

Details

Model specification is done via this object for `siena`, which calls function `simstats0c`. This function creates an object with the elements required to control the Robbins-Monro algorithm. Those not available as arguments can be changed manually when desired.
The matrix `D` transforming deviations from targets to updates in the Robbins Monro steps are partially diagonalized if `diagonalize > 0`; and its between-dependent variable blocks are put to `0` if `splitDepvars=1`. Diagonalization is omitted for the update step immediately at the end of Phase if `splitDepvars=-1`.

The value `prML = 1` defines the defaults valid in RSiena up to version 1.3.16. For ML estimation with only one dependent variable, `prML = 2` may be more efficient.
If `prML` is given as a vector of 7 probabilities, these are, consecutively: the probabilities of inserting a diagonal step, deleting a diagonal step, permuting, inserting a CCP, deleting a CCP, inserting random missing, deleting random missing; the residual (1 minus the sum) is the probability of a move step.
Further information about the implementation of the algorithm is in
https://www.stats.ox.ac.uk/~snijders/siena/Siena_algorithms.pdf.
Some of the examples use `projname = NULL`; this is just for the sake of checking the examples, not necessarily intended for normal use.

Value

`set_model_saom` returns an object of class `sienaModel`, `set_algorithm_saom` returns an object of class `sienaAlgorithmSettings`, `set_output_saom` returns an object of class `sienaOutputOptions`, and `sienaAlgorithmCreate` returns an object of class
`sienaAlgorithm`, all being lists containing values implied by the parameters.

set_effect *Function to change the specification of a Siena model by setting various columns in an effects object.*

Description

This function provides an interface to change the specification of a Siena model by setting various columns in an effects object.
The function set_effect combines the functionality of setEffect and includeEffects. set_effect now is preferred. The oher two are kept for backward compatibility.

Usage

```
## S3 method for class 'sienaEffects'
set_effect(x, shortNames, type="eval",
            depvar=x$name[1], covar1="", covar2="",
            effect1=0, effect2=0, effect3=0, period=1, group=1,
            parameter=NULL, initialValue = 0, random=FALSE,
            timeDummy = ",",
            include=TRUE, fix=FALSE, test=FALSE, verbose=TRUE, ...)

setEffect(x, shortName, parameter = NULL,
```

```
fix = FALSE, test = FALSE, random=FALSE, initialValue = 0,
timeDummy = ",", include = TRUE,
name = x$name[1], type = "eval", interaction1 = "",
interaction2 = "", effect1=0, effect2=0, effect3=0,
period=1, group=1, character=FALSE, verbose = TRUE)
```

Arguments

x	a Siena effects object as created by make_specification
shortNames	A shortName or list of shortNames (all with or all without quotes) to identify the effect which should be changed.
shortName	A shortName to identify the effect which should be changed.
depvar	Name of dependent variable (network or behavior) for which interactions are being defined. Defaults to the first in the effects object.
covar1	Name of siena object where needed to completely identify the effect e.g. covariate name or behavior variable name.
covar2	Name of siena object where needed to completely identify the effect e.g. covariate name or behavior variable name.
parameter	Value of internal effect parameter. If NULL, no change is made.
fix	For fixing effects. Boolean required. Default FALSE.
test	For testing effects by score-type tests. Boolean required. Default FALSE.
random	For specifying that effects will vary randomly; used only in function sienaBayes in package multiSiena. Not relevant for RSiena at this moment. Boolean required. Default FALSE.
initialValue	Initial value for estimation. Default 0.
timeDummy	string: Comma delimited string of which periods to dummy. Alternatively, use includeTimeDummy.
include	Boolean. default TRUE, but can be switched to FALSE to turn off an effect.
name	Name of dependent variable (network or behavior) for which the effect is being modified. Defaults to the first in the effects object, which is the first dependent variable specified in make_data_rsiena.
type	Character string indicating the type of the effect to be changed : "rate", "eval", "endow", or "creation". Default "eval".
interaction1	Name of siena object where needed to completely identify the effect e.g. covariate name or behavior variable name.
interaction2	Name of siena object where needed to completely identify the effect e.g. covariate name or behavior variable name.
effect1	Only for shortName=unspInt, behUnspInt or contUnspInt, which means this is a user-defined interaction effect: effect1 is the row number in x of the first component of the interaction effect.
effect2	See effect1: second component of interaction effect.
effect3	See effect1: third component of interaction effect.
period	Number of period if basic rate. Use numbering within groups.

group	Number of group if basic rate. Only relevant for sienaGroup data sets.
character	Boolean: whether the short name is a character string.
verbose	Boolean: should the print of altered effects be produced.
...	Additional arguments, not used now.

Details

Recall from the help page for make_specification that a Siena effects object (class sienaEffects or sienaGroupEffects) is a data.frame; the rows in the data frame are the effects for this data set; some of the columns/variables of the data frame are used to identify the effect, other columns/variables define how this effect is used in the estimation.
The function set_effect can operate on several effects simultaneously, but in a less detailed way. Using set_effect for only one effect can change not only the value of the column include, but also those of initialValue and parm. The arguments shortName, name, type, interaction1, interaction2, effect1, effect2, effect3, period, and group should identify one effect completely.
(Not all of them are needed; see make_specification.)
The call of setEffect will set, for this effect, the column elements of the resulting effects object for parm, fix, test, randomEffects, initialValue, timeDummy, and include to the values requested.
For setEffect the shortName must not be set between quotes, unless character=TRUE.

The input names interaction1 and interaction2 for setEffect do not themselves refer to created interactions, but to dependence of the base effects on other variables in the data set. They are used to completely identify the effects.

A value for parameter should be given only if only one effect is specified in shortNames. If it is given, the occurrences of # in the original effect and function names are replaced by this value. If a value for parameter is not given, the current value of the internal effect parameter of this effect is used.

Value

An object of class sienaEffects or sienaGroupEffects. This will be an updated version of the input effects object, with one row updated. Details of the rows altered will be printed, unless verbose=FALSE.

                  type="rate", period=2)
myeff
```

`set_interaction` *Function to create user-specified interactions for a Siena model.*

Description

This function allows the user to include or exclude an interaction effect in a Siena effects object.

Usage

```
## S3 method for class 'sienaEffects'
set_interaction(x, shortNames, type="eval",
            depvar=x$name[1], covar1=rep("", 3), covar2=rep("", 3),
            initialValue = 0, random=FALSE,
            include=TRUE, fix=FALSE, test=FALSE, verbose=TRUE, ...)

includeInteraction(x, ..., include = TRUE, name = x$name[1],
    type = "eval", interaction1 = rep("", 3), interaction2 = rep("", 3),
    fix=FALSE, test=FALSE, random=FALSE,
    initialValue=0,
    character = FALSE, verbose = TRUE)
```

Arguments

`x`	A Siena effects object as created by `make_specification`, which is either an object of class `sienaEffects` or `sienaGroupEffects`.
`shortNames`	List of 2 or 3 shortNames to identify the effects which should be interacted.
`type`	Type of effects to be interacted.
`depvar`	Name of dependent variable (network or behavior) for which interactions are being defined. Defaults to the first in the effects object.

covar1	Vector of Siena objects where needed to completely identify the effect e.g. covariate name or behavior variable name. See the examples below. Trailing blanks may be omitted.
covar2	Vector of Siena objects where needed to completely identify the effect e.g. covariate name or behavior variable name. Trailing blanks may be omitted.
initialValue	Initial value for estimation. Default 0.
random	For specifying that the interaction effect will vary randomly; not relevant for RSiena at this moment. Boolean required. Default FALSE.
include	Boolean. default TRUE, but can be switched to FALSE to turn off an interaction.
fix	Boolean. Are the effects to be fixed at the value stored in x$initialValue or not.
test	Boolean. Are the effects to be tested or not (requires fix).
character	Boolean: are the effect names character strings or not.
verbose	Boolean: should the print of altered effects be produced.
...	for includeInteraction: 2 or 3 shortNames to identify the effects which should be interacted. Not used for set_interaction.
name	Name of dependent variable (network or behavior) for which interactions are being defined. Defaults to the first in the effects object.
interaction1	Vector of Siena objects where needed to completely identify the effect e.g. covariate name or behavior variable name. See the examples below. Trailing blanks may be omitted.
interaction2	Vector of Siena objects where needed to completely identify the effect e.g. covariate name or behavior variable name. Trailing blanks may be omitted.

Details

The details provided should uniquely identify two or three effects. If so, an interaction effect will be created and included or not in the model.
Whether interactions between two or three given effects can be created depends on their interactionType (which can be, for dependent network variables, empty, ego, or dyadic; and for dependent behavioral variables, empty or OK). Consult the section on Interaction Effects in the manual for this. The interactionType is shown in the list of effects obtained from the function effectsDocumentation.
The short names must not be set between quotes, unless you use character=TRUE.
From the point of view of model building it is usually advisable, when including an interaction effect in a model, also to include the corresponding main effects. This is however not enforced by set_interaction.

As from version 1.3.24, effects object have a "version" attribute. Effects objects including interaction effects are not necessarily compatible between versions of RSiena. Therefore it is recommended to create such effects objects again when changing to a new version of RSiena. If an effects object including any interaction effects is used from an old version of RSiena, this will lead to a warning when running siena07.

An interaction effect does not have its own internal effect parameter. The internal effect parameters of the interacting main effects are used, whether or not these are included in the model. This implies that if an interaction effect is included but not the corresponding main effects, or not all of them, then nevertheless the internal effect parameters as specified in the effects object are used for the interaction. These can be set using function `setEffect` with the desired value of `parameter` and (in this case) `include=FALSE` or `fix=TRUE, initialValue=0`.
If an internal effect parameter is changed for one of the main effects after the last call of `set_interaction` for a given interaction effect, this will not be visible in the name of the interaction effect when the effects object is printed. However, the correct value of the internal effect parameter will be used by `siena07`.
The values of the internal effect parameters can be checked for a `sienaFit` object `ans` produced by `siena07` by looking at `ans$effects`, which is the requested effects object to which the main effects of the user-defined interactions were added, if they were not included.

Interaction effects are constructed from effects with shortName `unspInt` (for networks), `behUnspInt` (for discrete behavior), and `contUnspInt` (for continuous behavior) by specifying their elements `effect1` and `effect2`, and possibly `effect3`. The shortName is not altered by this function.

The number of possible user-specified interaction effects is limited by the parameters `nintn` (for dependent network variables) and `behNintn` (for dependent behavior variables) in the call of `make_specification`, which determine the numbers of effects with shortNames `unspInt`, `behUnspInt`, and `contUnspInt` (for the latter two, the maximum is `behNintn` each).

The input names `interaction1` and `interaction2`, which are vectors as indicated above, do not themselves refer to created interactions, but to dependence of the base effects on other variables in the data set. They are used to completely identify the effects.
The first element of these vectors applies to the first shortName, the second to the second, and if ... contains 3 shortNames, the third to the third. See the list of examples below for the interaction between `recip` and `simX` for an example.

Further information about Siena effects objects is given in the help page for `make_specification`.

A list of all effects in a given effects object (e.g., `myeff`), including their names of dependent variables, effect names, short names, and values of interaction1 and interaction2 (if any), is obtained by executing `effectsDocumentation(myeff)`.

Value

An updated version of the input effects object; if `include`, containing the interaction effect between "effect1" and "effect2" and possibly "effect3"; if not, without this interaction effect. The shortName of the interaction effect is "unspInt" for network effects, "behUnspInt" for discrete behavior effects, and "contUnspInt" for continuous behavior effects.
If `verbose=TRUE`, the interacting effects and the interaction effect will be printed, with their row numbers in the effects object.

siena *Function to estimate parameters in a Siena model*

Description

Estimates parameters in a Siena model using Method of Moments, based on direct simulation, conditional or otherwise; or using Generalized Method of Moments; or using Maximum Likelihood by MCMC simulation. Estimation is done using a Robbins-Monro algorithm.
`siena()` and `siena07()` perform the same estimation. The first of these is preferred, the other is kept for backward compatibility.

Usage

```
siena(data=NULL, effects=NULL,
        control_model=NULL, control_algo=NULL, control_out=NULL,
        thetaBound = 50,
        returnDeps = FALSE,
        batch = FALSE, verbose = FALSE, silent=TRUE,
```

```
        initC=TRUE,
        nbrNodes = 1, clusterString=rep("localhost", nbrNodes),
        clusterType=c("PSOCK", "FORK"), cl=NULL, ...)

siena07(alg, batch=FALSE, verbose=FALSE, silent=FALSE,
        useCluster=FALSE, nbrNodes=2,
        thetaValues = NULL,
        returnThetas = FALSE,
        thetaBound = 50,
        targets = NULL,
        initC=TRUE, clusterString=rep("localhost", nbrNodes), tt=NULL,
        parallelTesting=FALSE, clusterIter=!alg$maxlike,
        clusterType=c("PSOCK", "FORK"), cl=NULL, ...)
```

Arguments

data	Siena data set of class sienadata.
effects	sienaEffects object specifying which effects are included the model.
control_model	Control object for the model, of class sienaModel.
control_algo	Control object for the algorithm, of class sienaAlgorithmSettings.
control_out	Control object for the output, of class sienaOutputOptions.
thetaBound	Numeric: if at some moment during estimation the maximum absolute value of the parameters exceeds thetaBound, estimation is interrupted. In interactive use, the user is requested to give a higher number; if non-numeric input is given, estimation stops. In non-interactive use, estimation stops anyway. The check is turned off by using thetaBound=Inf.
returnDeps	Boolean. Whether to return the simulated networks in Phase 3.
batch	Desired interface: FALSE gives a gui (graphical user interface implemented as a tcl/tk screen), TRUE gives a small (if verbose=FALSE) amount of printout to the console.
verbose	Produces various output to the console if TRUE.
silent	Produces no output to the console if TRUE, even if batch mode.
initC	Boolean: set to TRUE if the simulation will use C routines (currently always needed). Only for use if using multiple processors, to ensure all copies are initialised correctly. Ignored otherwise, so is set to TRUE by default.
nbrNodes	Number of processes to use; when using siena07, this is ignored if useCluster is FALSE.
clusterString	Definitions of clusters. Default set up to use the local machine only.
clusterType	Either "PSOCK" or "FORK". On Windows, must be "PSOCK". On a single non-Windows machine may be "FORK", and subprocesses will be formed by forking. If "PSOCK", subprocesses are formed using R scripts.
cl	An object of class c("SOCKcluster", "cluster") (see Details).
alg	A control object, of class sienaAlgorithm.

`useCluster` Boolean: whether to use a cluster of processes (useful if multiple processors are available).

`thetaValues` If not `NULL`, this should be a matrix with parameter values to be used in Phase 3. The number of columns must be equal to the number of estimated parameters in the effects object (if conditional estimation is used, without the rate parameters for the conditioning dependent variable). Can only be used if `alg$simOnly=TRUE`.

`returnThetas` Boolean: whether to return theta values and generated estimation statistics of Phase 2 runs.

`targets` Numeric vector of length equal to the number of estimated parameters, meant to supersede the targets calculated from the data set; see "Details". Not for regular use.

`tt` A `tcltk` toplevel window. Used if called from the model options screen, if `tcltk` is available.

`parallelTesting`
Boolean. If `TRUE`, sets up random numbers to parallel those in Siena 3.

`clusterIter` Boolean. If `TRUE`, multiple processes execute complete iterations at each call. If `FALSE`, multiple processes execute a single wave at each call.

`...` Arguments for the simulation function, see `simstats0c`:
`prevAns` if a previous reasonable provisional estimate was obtained for a similar model;
the following are ignored by `siena` (because included here or in `control_out`) but can be mentioned when using `siena07`:
in any case, `data` and `effects`, as in the examples below;
possibly also `returnDeps` if the simulated dependent variables (networks, behaviour) should be returned;
possibly also `returnChains` or `returnChangeContributions` if the simulated sequences (chains) of ministeps or the simulated change statistics (contributions) should be returned; this may produce a very big file.

Details

This is the main function and workhorse of `RSiena`.

For use of `siena07`, it is necessary to specify parameters `data` (RSiena data set) and `effects` (effects object), which are required parameters in function `simstats0c`. (These parameters are inserted through '...'.) See the examples.

`siena` runs a Robbins-Monro algorithm for parameter estimation using the three-phase implementation described in Snijders (2001, 2017), with (if `findiff=FALSE` in `control_algo`) derivative estimation as in Schweinberger and Snijders (2007). The default is estimation according to the Method of Moments as in Snijders, Steglich and Schweinberger (2007).
If `gmm=TRUE` in `control_algo` and `myeff` contains one or more `gmm` statistics as included by function `includeGMoMStatistics`, the algorithm employs the Generalized Method of Moments as defined in Amati, Schoenenberger, and Snijders (2015, 2019).
For continuous behavior variables defined with `type="continuous"` in `as_dependent_rsiena`, estimation is done as described in Niezink and Snijders (2017).
If `maxlike=TRUE` in `control_algo`, estimation is done by Maximum Likelihood implemented as in Snijders, Koskinen and Schweinberger (2010).

Phase 1 does a few iterations to estimate the derivative matrix of the targets with respect to the parameter vector. Phase 2 does the estimation. Phase 3 runs a simulation to estimate standard errors and check convergence of the model. The simulation function is called once for each iteration in these phases and also once to initialise the model fitting and once to complete it. Unless in batch mode, a tcl/tk screen is displayed to allow interruption and to show progress.

If `targets` is specified in `control_algo` or in the call of `siena07` (which should be done only in special cases), and provided that estimation is by the Method of Moments, the data is not a multi-group data set and has exactly 2 waves, and if the length of the vector `targets` is equal to the number of estimated parameters (not counting the rate parameters estimated by conditional estimation), then the vector `targets` supersedes the targets calculated from the data set.

It is necessary to check that convergence has been achieved. The rule of thumb is that the all t-ratios for convergence should be in absolute value less than 0.1 and the overall maximum convergence ratio should be less than 0.25. If this was not achieved, the result can be used to start another estimation run from the estimate obtained, using the parameter `prevAns` as illustrated in the example below. (This parameter is inserted through '...' into the function `initializeFRAN`.)

For good estimation of standard errors, it is necessary that `n3` in `control_algo` is large enough. More about this is in the manual. The default value `n3` is adequate for most explorative use, but for presentation in publications larger values are necessary, depending on the data set and model; e.g., `n3=3000` or larger.

Parameters can be tested against zero by dividing the estimate by its standard error and using an approximate standard normal null distribution. Further, function `test_parameter` is available for multi-parameter testing.
Parameters specified in `set_effect` with `fix=TRUE, test=TRUE` will not be estimated; score tests of their hypothesized values can be obtained using `test_parameter` with `method="score"`.

If `simOnly=TRUE` in `control_algo`, which is meant to go together with `nsub=0`, the calculation of the standard errors and covariance matrix at the end of Pase 3 is skipped. No estimation is performed. If `thetaValues` in `control_algo` is not `NULL`, the parameter values in the rows of this matrix will be used in the consecutive runs of Phase 3. If `n3` is larger than the number of rows times `nbrNodes` (see below), the last row of `thetaValues` will continue to be used. The parameter values actually used will be stored in the output matrix `thetaUsed`.

Multiple processors are used for estimation by MoM to distribute each iteration in each subphase over the cluster of nodes. The number of iterations accordingly will be divided (approximately) by the number of nodes; for phase 2, unless `n2start` is specified in `control_algo`. This implies that if multiple processors are used, think of dividing `n2start` by `nbrNodes`.
For estimation by ML, multiple processing is done per period. Therefore, for one period (two waves) and one group, this will have no effect.

In the case of using multiple processors, there are two options for telling `siena` or `siena07` to use them. By specifying the options `useCluster`, `nbrNodes`, `clusterString` and `initC`, the estimation will create a `cluster object` that will be used by the `parallel` package. After finishing the estimation procedure, the estimation will automatically stop the cluster. Alternatively, instead of having the function to create a cluster, the user may provide its own by specifying the option `cl`, similar to what the boot function does in the **boot** package. By using the option `cl` the user may be able to create more complex clusters (see examples below).

If `thetaValues` is not `NULL` and `nbrNodes >= 2`, parameters in Phase 3 will be constant for each set of `nbrNodes` consecutive simulations. This must be noted in the interpretation, and will be visible in `thetaUsed` (see below).

The keyword thetaBound is used because in practice, parameter values of Stochastic Actor-oriented Models will be limited in magnitude, and for usual models values larger than 50 never occur, which means that when they occur this may be regarded as a signal of divergence of the algorithm.
Note that covariates should have large enough standard deviations for parameters to have moderate values; see the manual.

Value

Returns an object of class sienaFit, some parts of which are:

OK	Boolean indicating successful termination
termination	Character string, values: "OK", "Error", or "UserInterrupt". "UserInterrupt" indicates that the user asked for early termination before phase 3.
f	Various characteristics of the data and model definition.
requestedEffects	The included effects in the effects object.
effects	The included effects in the effects object to which are added the main effects of the requested interaction effects, if any.
theta	Estimated value of theta, if simOnly=FALSE in control_algo.
thetas	Matrix, returned if returnThetas and x$nsub >= 1. First column is subphase; further columns are values of theta as generated during this subphase of Phase 2.
sfs	Matrix, returned if returnThetas and x$nsub >= 1. First column is subphase; further columns are deviations from targets generated during this subphase of Phase 2.
covtheta	Estimated covariance matrix of theta; this is not available if x$simOnly=TRUE.
se	Vector of standard errors of estimated theta, if x$simOnly=FALSE.
dfra	Matrix of estimated derivatives.
sf	Matrix of simulated deviations from targets in phase 3.
sf2	Array of periodwise deviations from simulations in phase 3. Not included if x$lessMem=TRUE.
W	If x$gmm=TRUE: Estimated optimal matrix of weights for estimation by the Generalized Method of Moments.
B	If x$gmm=TRUE: Row-normalized matrix of weights for equating the linear combination of estimation statistics to 0, for estimation by the Generalized Method of Moments.
tconv	t-statistics for convergence.
tmax	maximum absolute t-statistic for convergence for non-fixed parameters.
tconv.max	overall maximum convergence ratio.
ac3	If x$maxlike=TRUE: autocorrelations of statistics in Phase 3.
targets	Observed statistics; for ML, zero vector.
targets2	Observed statistics by wave, starting with second wave; for ML, zero matrix.

ssc	Score function contributions for each wave for each simulation in phase 3. Not included if finite difference method is used or if x$lessMem=TRUE.
scores	Score functions, added over waves, for each simulation in phase 3. Only included if x$lessMem=FALSE.
regrCoef	If x$dolby and not x$maxlike: regression coefficients of estimation statistics on score functions.
regrCor	If x$dolby and not x$maxlike: correlations between estimation statistics and score functions.
estMeans	Estimated means of estimation statistics.
estMeans.sem	If x$simOnly: Standard errors of the estimated means of estimation statistics.
sims	If returnDeps=TRUE: list of simulated dependent variables (networks, behaviour). Networks are given as a list of edgelists, one for each period. The structure of sims is a nested list: sims[[run]][[group]][[dependent variable]][[period]]. If x$maxlike=TRUE and there is only one group and one period, the structure is [[run]][[dependent variable]].
chain	If returnChains = TRUE: list, or data frame, of simulated chains of ministeps. The chain has the structure chain[[run]][[depvar]][[period]][[ministep]].
changeContributions	If returnChangeContributions = TRUE: list, or data frame, of simulated change contributions. The contributions have the structure returnChangeContributions[[run]][[depvar]][[period]][[m
Phase3nits	Number of iterations actually performed in phase 3.
thetaUsed	If thetaValues is not NULL, the matrix of parameter values actually used in the simulations of Phase 3.

Writes text output to the file indicated for siena in control_output and for siena07 in alg.

`sienaFit.methods` *Methods for processing sienaFit objects, produced by* `siena`

Description

`print`, `summary`, and `xtable` methods for `sienaFit` objects.

Usage

```
## S3 method for class 'sienaFit'
print(x, tstat=TRUE, ...)
```

```
## S3 method for class 'sienaFit'
summary(object, ...)

## S3 method for class 'summary.sienaFit'
print(x, matrices=TRUE, ...)

## S3 method for class 'sienaFit'
coef(object, dropRates=TRUE, shortenNames=TRUE, ...)

## S3 method for class 'sienaFit'
vcov(object, dropRates=TRUE, shortenNames=TRUE, ...)

## S3 method for class 'sienaFit'
write_result(x, type="tex",
    fileName=NULL,
    vertLine=TRUE, tstatPrint=FALSE, sig=FALSE, d=3, ...)

## S3 method for class 'sienaFit'
xtable(x, caption = NULL, label = NULL, align = NULL,
    digits = NULL, display = NULL, ...)

siena_table(x, type="tex",
    fileName=NULL,
    vertLine=TRUE, tstatPrint=FALSE, sig=FALSE, d=3, nfirst=NULL)
```

Arguments

x	An object of class sienaFit, or summary.sienaFit as appropriate. For siena_table, objects of class sienaBayes are also permitted.
object	An object of class sienaFit, produced by siena. For siena_table, objects of class sienaBayes are also permitted.
dropRates	Logical. Should the results for the basic rate parameters also be given?
shortenNames	Logical. Should the effect names be shortened?
matrices	Boolean: whether also to print in the summary the covariance matrix of the estimates, the derivative matrix of expected statistics X by parameters, and the covariance matrix of the statistics.
tstat	Boolean: if this is NULL, the t-statistics for convergence will not be added to the report.
type	Type of output to produce; must be either "tex" or "html".
fileName	Name of the file; defaults to the name of the sienaFit object. "" indicates output to the console.
vertLine	Boolean: add vertical lines separating the columns in siena_table.
tstatPrint	Boolean: add a column of significance t values (parameter estimate/standard error estimate) to siena_table.
sig	Boolean: adds symbols (daggers and asterisks) indicating significance levels for the parameter estimates to siena_table.

d	The number of decimals places used in siena_table.
caption	See documentation for xtable.
label	See documentation for xtable.
align	See documentation for xtable.
digits	See documentation for xtable.
display	See documentation for xtable
nfirst	Only relevant for the multiSiena package.
...	Add extra parameters for print.xtable here. e.g. type, file.

Value

Function coef.sienaFit gives the estimated parameters, and vcov.sienaFit their estimated variance-covariance matrix.

The function print.sienaFit prints a table containing estimated parameter values, standard errors and (optionally) t-statistics for convergence.

The function summary.sienaFit prints a table containing estimated parameter values, standard errors and t-statistics for convergence together with the covariance matrix of the estimates, the derivative matrix of expected statistics X by parameters, and the covariance matrix of the expected statistics X.

The function xtable.sienaFit creates an object of class xtable.sienaFit which inherits from class xtable and passes an extra arguments to the print.xtable.

The function siena_table outputs a latex or html table of the estimates and standards errors of a sienaFit object. The table will be written to a file in the current directory and has a footnote reporting the maximum of the convergence t-ratios. Endowment or creation effects will be denoted, respectively, by 'maintenance' or 'creation'.

See the manual for how to import the html tables easily into MS-Word.

`simstats0c` *Versions of FRAN*

Description

The functions to be called as "FRAN" by `siena` and `siena07`. They call compiled C++. Not for general users' use.

Usage

```
simstats0c(z, x, data=NULL, effects=NULL, fromFiniteDiff=FALSE,
           returnDeps=FALSE, returnChains=FALSE,
           returnChangeContributions=FALSE,
           byWave=FALSE, returnDataFrame=FALSE, returnLoglik=FALSE)
maxlikec(z, x, data=NULL, effects=NULL,
           returnChains=FALSE, byGroup = FALSE,
           byWave=FALSE, returnDataFrame=FALSE,
           returnLoglik=FALSE, onlyLoglik=FALSE)
initializeFRAN(z, x, data, effects, prevAns=NULL, initC,
           profileData=FALSE, returnDeps=FALSE, returnChains=FALSE,
           returnChangeContributions=FALSE,
           byGroup=FALSE, returnDataFrame=FALSE,
           byWave=FALSE, returnLoglik=FALSE, onlyLoglik=FALSE)
terminateFRAN(z, x)
```

Arguments

`z`	Control object, passed in automatically in `siena`.
`x`	A sienaAlgorithm object, passed in automatically in `siena`.
`data`	A `sienadata` object as returned by `make_data_rsiena`.
`effects`	A sienaEffects object as returned by `make_specification`.
`fromFiniteDiff`	Boolean used during calculation of derivatives by finite differences. Not for user use.
`returnDeps`	Boolean. Whether to return the simulated networks in Phase 3.

`returnChains` Boolean. Whether to return the chains.

`returnChangeContributions`
Boolean. Whether to return the change contributions.

`byWave` Boolean. Whether to return the finite difference or maximum likelihood derivatives by wave (uses a great deal of memory). Only necessary for `test_time`

`byGroup` Boolean. For internal use: allows different thetas for each group to be used in `sienaBayes`.

`returnDataFrame`
Boolean. Whether to return the chains as lists or data frames.

`returnLoglik` Boolean. Whether to return the log likelihood of the simulated chain.

`onlyLoglik` Boolean: whether to return just the likelihood for the simulated chain, plus details of steps accepted and rejected.

`prevAns` An object of class "sienaFit" as returned by `siena`, from which scaling information (derivative matrix and standard deviation of the deviations) will be extracted along with the latest version of the parameters which will be used as the initial values, unless the model requests the use of standard initial values. If the previous model is exactly the same as the current one, Phase 1 will be omitted. If not, any parameter estimates for effects which are included in the new model will be used as initial values, but phase 1 will still be carried out. If the results used as `prevAns` are a reasonable starting point, this will increase the efficiency of the algorithm.

`initC` If TRUE, call is to setup the data and model in C++. For use with multiple processes only.

`profileData` Boolean to force dumping of the data for profiling with `sienaProfile.exe`.

Details

Not for general users' use.
The name of `simstats0c` or `maxlikec` should be used for the element FRAN of the model object, the former when using estimation by forward simulation, the latter for maximum likelihood estimation. The arguments with no defaults must be passed in on the call to `siena`. `initializeFRAN` and `terminateFRAN` are called in both cases.

Value

`simstats0c` returns a list containing:

`fra` Simulated statistics.

`sc` Scores with which to calculate the derivative (not phase 2 or if using finite differences or maximum likelihood).

`dff` Contributions to the derivative if finite differences

`ntim` For conditional processing, time taken.

`feasible` Currently set to TRUE.

`OK` Could be set to FALSE if serious error has occurred.

`sims` A list of simulation results, one for each period. Each list consists of a list for each data object, each of which consists of a list for each network, each of which consists of a list for each period, each component of which is an edgelist in matrix form (the columns are from, to, value) (or vector for behavior variables). Only if `returnDeps` is TRUE.

`maxlikec` returns a list containing:

`fra` Simulated scores.

`dff` Simulated Hessians: stored as lower triangular matrices

`ntim` NULL, compatibility only

`feasible` Currently set to TRUE.

`OK` Could be set to FALSE if serious error has occurred.

`dff` Simulated Hessian

`sims` NULL, for compatibility only

`chain` A list of sampled chains, one for each period. Each list consists of a list for each data object, each of which consists of a list for each network, each of which consists of a list for each period, each component of which is a list or a data frame depending on the value of `returnDataFrame`. Only if `returnChains` is TRUE.

`changeContributions`
A list of sampled chains, one for each period. Each list consists a list for each dependent variable, each of which consists of a list for each period, each component of which is a matrix of effects times choices containing the changeContributions (+- change statistics) for each ministep.
Only if `returnChangeContributions` is TRUE.

`accepts` Number of accepted MH steps by dependent variable (permute steps are counted under first dependent variable)

`rejects` Number of rejected MH steps by dependent variable (permute steps are counted under first dependent variable)

`aborts` Number of aborted MH steps counted under first dependent variable.

`loglik` Loglikelihood of the simulations. Only if `returnLoglik` is TRUE.
If `onlyLoglik` is TRUE, only `loglik`, `accepts`, `rejects` and `aborts` are returned.

`initializeFRAN` and `terminateFRAN` return the control object `z`.

summary.iwlsm *Summary method for Iterative Weighted Least Squares Models*

Description

summary method for objects of class "iwlsm"

Usage

```
## S3 method for class 'iwlsm'
summary(object, method = c("XtX", "XtWX"),
 correlation = FALSE, ...)
```

Arguments

object	the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class iwlsm, in the sense that the components returned by the iwlsm function will be available.
method	Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?
correlation	logical. Should correlations be computed (and printed)?
...	arguments passed to or from other methods.

Details

This function is a method for the generic function summary() for class "iwlsm". It can be invoked by calling summary(x) for an object x of the appropriate class, or directly by calling summary.iwlsm(x) regardless of the class of the object.

Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the summary function.

correlation	The computed correlation coefficient matrix for the coefficients in the model.

`cov.unscaled`	The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.
`sigma`	The scale estimate.
`stddev`	A scale estimate used for the standard errors.
`df`	The number of degrees of freedom for the model and for residuals.
`coefficients`	A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.
`terms`	The terms object used in fitting this model.

test_gof *Functions to assess goodness of fit for SAOMs*

Description

The function sienaGOF assesses goodness of fit for a model specification as represented by an estimated sienaFit object created by siena. This is done by simulations of auxiliary statistics, that differ from the statistics used for estimating the parameters. The auxiliary statistics must be given explicitly.

The fit is good if the average values of the auxiliary statistics over many simulation runs are close to the values observed in the data. A Monte Carlo test based on the Mahalanobis distance is used to calculate frequentist p-values.

Plotting functions can be used to diagnose bad fit. There are basic functions for calculating auxiliary statistics available out of the box, and the user is invited to create additional ones.

test_gof and sienaGOF perform the same estimation. The first of these is preferred, the other is kept for backward compatibility.

Usage

```
## S3 method for class 'sienaFit'
test_gof(object, auxiliaryFunction,
    period=NULL, verbose=FALSE, join=TRUE, twoTailed=FALSE,
    cluster=NULL, robust=FALSE, groupName="Data1",
    varName, tested=FALSE, iterations=NULL, giveNAWarning=TRUE, ...)

sienaGOF(object, auxiliaryFunction,
    period=NULL, verbose=FALSE, join=TRUE, twoTailed=FALSE,
    cluster=NULL, robust=FALSE, groupName="Data1",
    varName, tested=FALSE, iterations=NULL, giveNAWarning=TRUE, ...)
## S3 method for class 'sienaGOF'
plot(x, center=FALSE, scale=FALSE, violin=TRUE, key=NULL,
    perc=.05, period=1, showAll=FALSE, position=4, fontsize=12, ...)
## S3 method for class 'sienaGOF'
descriptives(x, center=FALSE, scale=FALSE, perc=.05, key=NULL,
    period=1, showAll=FALSE, ...)
```

Arguments

object	An object of class sienaFit, produced by a call to siena with returnDeps = TRUE and maxlike=FALSE (the latter is the default, the former is not); or a list of such objects; if a list, then the first period of each sienaFit object will be used. If this is a list of sienaFit objects, where object is mentioned below, it refers to the first element of this list.
auxiliaryFunction	Function to be used to calculate the auxiliary statistics; this can be a user-defined function, e.g. depending on the sna or igraph packages.

	See Examples and test_gof_auxiliary for more information on the signature of this function. The basic signature is function(index, data, sims, period, groupName, varName, ...), where index is the index of the simulated network, or NULL if the observed variable is needed; data is the observed data object from which the relevant variables are extracted; sims is the list of simulations returned from siena; period is the index of the period; and ... are further arguments (like levls in the examples below and in test_gof_auxiliary).
period	Vector of period(s) to be used (may run from 1 to number of waves - 1). Has an effect only if join=FALSE. May be only a single number if object is a list of sienaFit objects.
verbose	Whether to print intermediate results. This may give some peace of mind to the user because calculations can take some time.
join	Boolean: should sienaGOF do tests on all of the periods individually (FALSE), or sum across periods (TRUE)?
twoTailed	Whether to use two tails for calculating p-values on the Monte Carlo test. Recommended for advanced users only, as it is probably only applicable in rare cases.
cluster	Optionally, a parallel or snow cluster to execute the auxiliary function calculations on.
robust	Whether to use robust estimation of the covariance matrix.
groupName	Name of group; relevant for multi-group data sets.
varName	Name of dependent variable.
tested	A logical vector of length object$pp (number of parameters), indicating a subset of tested parameters; or NULL, indicating all tested parameters (see below); or FALSE, indicating nothing is to be tested.
iterations	Number of iterations for the goodness of fit calculations. If NULL, the number of simulated data sets in object.
giveNAWarning	If TRUE, a warning is given if any simulated values are missing.
x	Result from a call to sienaGOF.
center	Whether to center the statistics by median during plotting.
scale	Whether to scale the statistics by range during plotting. scale=TRUE makes little sense without also center=TRUE.
violin	Use violin plots (vs. box plots only)?
key	Keys in the plot for the levels of the auxiliary statistic (as given by parameter levls in the examples).
perc	1 minus confidence level for the confidence bands (two sided).
position	Position where the observed value is plotted: 1=under, 2=to the left, 3=above, 4=to the right of the red dot. Can be a single number from 1 to 4, or a vector with positions for each statistic (possibly recycled).
fontsize	Font size for the observed values plotted.

...	Other arguments; for test_gof, e.g., levls as a parameter for the auxiliary statistic in test_gof_auxiliary; for plot.sienaGOF(), e.g., the usual plotting parameters main, xlab, ylab, cex, cex.main, cex.lab, and cex.axis.
showAll	If FALSE, drops statistics with variance 0.

Details

This function is used to assess the goodness of fit of an estimated stochastic actor-oriented model for an arbitrarily defined multidimensional auxiliary statistic. It operates basically by comparing the observed values, at the ends of the periods, with the simulated values for the ends of the periods. The differences are assessed by combining the components of the auxiliary statistic using the Mahalanobis distance.

For sienaFit objects that were made for a multi-group data set, if you are not sure about the groupNames to use, these can be retrieved by the command "names(dataObject)" (where dataObject is the data used to produce the input object). Mostly they are "Data1", "Data2", etc.

To save computation time, iterations can be set to a lower number than what is available in object; this will yield a less precise result.

The function does not work properly for data sets that include a sienaCompositionChange object. If you wish to test the fit for such a data set, you need (for the purpose of fit assessment only) to replace the data set by a data set where absent actors are represented by structural zeros, and estimate the same model for this data set with the corresponding effects object, and use sienaGOF for this sienaFit object.

To achieve comparability between simulated and observed dependent variables, variables that are missing in the data at the start or end of a period are replaced by 0 (for tie variables) or NA (for behavior variables).
If there are any differences between structural values at the beginning and at the end of a period, these are dealt with as follows. For tie variables that have a structural value at the start of the period, this value is used to replace the observed value at the end of the period (for the goodness of fit assessment only). For tie variables that have a structural value at the end of the period but a free value value at the start of the period, the reference value for the simulated values is lacking; therefore, the simulated values at the end of the period then are replaced by the structural value at the end of the period (again, for the goodness of fit assessment only).

The auxiliary statistics documented in test_gof_auxiliary are calculated for the simulated dependent variables in Phase 3 of the estimation algorithm, returned in object because of having used returnDeps = TRUE in the call to siena. These statistics should be chosen to represent features of the network that are not explicitly fit by the estimation procedure but can be considered important properties that the model at hand should represent well. Some examples are:

- Outdegree distribution
- Indegree distribution
- Distribution of the dependent behavior variable (if any).
- Distribution of geodesic distances
- Triad census
- Edgewise homophily counts

- Edgewise shared partner counts
- Statistics depending on the combination of network and behavioral variables.

The function is written so that the user can easily define other functions to capture some other relevant aspects of the network, behaviors, etc.
This is further illustrated in the help page test_gof_auxiliary.

We recommend the following heuristic approach to model checking:

1. Check convergence of the estimation.
2. Assess goodness of fit (primarily using join=TRUE) on auxiliary statistics, and if necessary refine the model.
3. Assess time heterogeneity by sienaTimeTest and if there is evidence for time heterogeneity either modify the base effects or include time dummy terms.

No general rules can be given about whether time heterogeneity (test_time) or goodness of fit using test_gof have precedence. This is an explorative issue.

The summary function will display some useful information to help with model selection if some effects are set in the effects object to be fixed and tested. In that case, for all parameters indicated in the vector tested, a rough estimator is computed for the Mahalanobis distance that would be obtained at each proposed specification. This is then given in the summary. This can help guide model selection. This estimator is called the modified Mahalanobis distance (MMD). See Lospinoso and Snijders (2019) or the manual for more information.

The following functions are pre-fabricated for ease of use, and can be passed in as the auxiliaryFunction with no extra effort; see test_gof_auxiliary and the examples below.

- IndegreeDistribution
- OutdegreeDistribution
- BehaviorDistribution
- TriadCensus
- mixedTriadCensus
- dyadicCov

Value

The result is of class sienaGOF; this is a list of elements of class sienaGofTest; if join=TRUE, the list has length 1; if join=FALSE, each list element corresponds to a period analyzed; the list elements are themselves lists again, including the following elements:

- sienaFitName The name of the input object.
- auxiliaryStatisticName
  The name of auxiliaryFunction.
- Observations The observed values for the auxiliary statistics.
- Simulations The simulated auxiliary statistics.
- ObservedTestStat
  The observed Mahalanobis distance in the data.

- `SimulatedTestStat` The Mahalanobis distance for the simulations.
- `TwoTailed` Whether the p-value corresponds to a one- or two-tailed Monte Carlo test.
- `p` The p-value for the observed Mahalanobis distance in the permutation distribution of the simulated Mahalanobis distances.
- `Rank` Rank of the covariance matrix of the simulated auxiliary statistics.

In addition there are several attributes which give, for model specifications with fixed-and-tested effects, approximations to the expected Mahalanobis distance for model specifications where each of these effects would be added. This is reported in the `summary` method.
The `plot` method makes violin plots or box plots, with superimposed confidence bands, for the simulated distributions of all elements of the `auxiliaryFunction`, with the observed values indicated by red dots; but statistics with variance 0 are dropped.
`sienaGOF` objects can also be plotted by package `autograph`.

`descriptives.sienaGOF` returns a matrix giving numerical information about what is plotted in the `plot` method: maximum, upper percentile, mean, median, lower percentile, minimum, and standard deviation of the simulated distributions of the auxiliary statistics, the observed values, and the proportions of simulated values greater and greater-or-equal than the observed values. If `center=TRUE` the median is subtracted from mean, median, and percentiles; if `scale=TRUE` these numbers and the standard deviation are divided by (maximum - minimum).
If `showAll=FALSE`, statistics with variance 0 will be dropped.

test_gof_auxiliary *Auxiliary functions for goodness of fit assessment by* test_gof

---

Description

The functions given here are auxiliary to function test_gof which assesses goodness of fit for actor-oriented models.

The auxiliary functions are, first, some functions of networks or behaviour (i.e., statistics) for which the simulated values for the fitted model are compared to the observed value; second, some extraction functions to extract the observed and simulated networks and/or behaviour from the sienaFit object produced by siena with returnDeps=TRUE.

These functions are exported here mainly to enable users to write their own versions. At the end of this help page some non-exported functions are listed. These are not exported because they depend on packages that are not in the R base distribution; and to show templates for readers wishing to contruct their own functions.

Usage

```
OutdegreeDistribution(i, obsData, sims, period, groupName, varName,
         levls=0:8, cumulative=TRUE)

IndegreeDistribution(i, obsData, sims, period, groupName, varName,
         levls=0:8, cumulative=TRUE)

BehaviorDistribution(i, obsData, sims, period, groupName, varName,
         levls=NULL, cumulative=TRUE)

TriadCensus(i, obsData, sims, period, groupName, varName, levls=1:16)

mixedTriadCensus(i, obsData, sims, period, groupName, varName)

dyadicCov(i, obsData, sims, period, groupName, varName, dc)

egoAlterCombi(i, obsData, sims, period, groupName, varName, trafo=NULL)
```

```
egoAlterCovarComb(i, obsData, sims, period, groupName, varName, covar)

sparseMatrixExtraction(i, obsData, sims, period, groupName, varName)

networkExtraction(i, obsData, sims, period, groupName, varName)

behaviorExtraction(i, obsData, sims, period, groupName, varName)
```

Arguments

i	Index number of simulation to be extracted, ranging from 1 to `length(sims)`; if NULL, the data observation will be extracted.
obsData	The observed data set to which the model was fitted; normally this is `x$f` where `x` is the `sienaFit` object for which the fit is being assessed.
sims	The simulated data sets to be compared with the observed data; normally this is `x$sims` where `x` is the `sienaFit` object for which the fit is being assessed.
period	Period for which data and simulations are used (may run from 1 to number of waves - 1).
groupName	Name of group; relevant for multi-group data sets; defaults in `test_gof` to `"Data1"`.
varName	Name of dependent variable.
levls	Levels used as values of the auxiliary statistic. For `BehaviorDistribution`, this defaults to the observed range of values.
cumulative	Are the distributions to be considered as raw or cumulative (<=) distributions?
dc	Dyadic covariate: either a matrix with dimensions $n \times n$; or, as period-dependent values, an array with dimensions $n \times n \times (M-1)$; where n is the number of actors and M is the number of waves. There may be more time points, but those after $(M-1)$ will not be used.
trafo	For `egoAlterCombi`: transformation of the dependent behavior variable. Default: identity function.
covar	For `egoAlterCovarComb`: arbitrary monadic variable, vector of length n, the number of actors.

Details

The statistics should be chosen to represent features of the network that are not explicitly fit by the estimation procedure but can be considered important properties that the model at hand should represent well. The three given here are far from a complete set; they will be supplemented in due time by statistics depending on networks and behavior jointly. The examples below give a number of other statistics, using the packages `sna` and `igraph`.

The `levls` parameter must be adapted to the range of values that is considered important. For indegrees and outdegrees, the whole range should usually be covered. If the range is large, which could be the case, e.g., for indegrees of two-mode networks where the second mode has few nodes, think about the possibility of making a selection such as `levls=5*(0:20)` or `levls=c(0:4,5*(1:20))`; which in most cases will make sense only if `cumulative=TRUE`.

The method signature for the auxiliary statistics generally is
`function(i, obsData, sims, period, groupName, varName, ...)`. For constructing new auxiliary statistics, it is helpful to study the code of `OutdegreeDistribution`, `IndegreeDistribution`, and `BehaviorDistribution` and of the example functions below.

`TriadCensus` returns the distribution of the Holland-Leinhardt triad census according to the algorithm by Batagelj and Mrvar (implementation by Parimalarangan, Slota, and Madduri). An alternative is the `TriadCensus.sna` function mentioned below, from package `sna`, which gives the same results. Here the `levls` parameter can be used to exclude some triads, e.g., for non-directed networks.
The Batagelj-Mrvar algorithm is optimized for sparse, large graphs and may be much faster than the procedure implemented in `sna`. For dense graphs the `sna` procedure may be faster.

`dyadicCov` assumes that `dc` is a categorical dyadic variable, and returns the frequencies of the non-zero values for realized ties. It is recommended to do this for a categorical covariate. Since zero values of dc are not counted, it may be advisable to code dc so that all non-diagonal values are non-zero, and all diagonal values are zero.

`egoAlterCombi` returns the frequencies of realized ties for each ego-alter combination of values of the dependent behavior variable, transformed by trafo; if `NULL`, untransformed.
The range of this transformation should preferably have 5 or fewer values, and definitely not 10 or more, as this would lead to problems in the coding of ego-alter combinations.
`egoAlterCovarComb` does the same, for arbitrary monadic variables; e.g., transformed or untransformed covariates.
Here also, the range of `covar` should preferably have 5 or fewer values. Missing values are allowed.

Value

`OutdegreeDistribution` returns a named vector, the distribution of the observed or simulated outdegrees for the values in `levls`.

`IndegreeDistribution` returns a named vector, the distribution of the observed or simulated indegrees for the values in `levls`.

`BehaviorDistribution` returns a named vector, the distribution of the observed or simulated behavioral variable for the values in `levls`.

`TriadCensus` returns a named vector, the distribution of the Holland-Leinhardt triad census according to the algorithm by Batagelj and Mrvar.

`mixedTriadCensus` returns a named vector, the distribution of the mixed triad census of Hollway, Lomi, Pallotti, and Stadtfeld (2017). See their Figure 1 for the meaning of the codes. In this figure, ties between the bottom nodes are for the first network, ties from the bottom to the top nodes are for the second network. The mixed triad census can be used for pairs of dependent networks of which the first must be one-mode and the second can be one-mode or two-mode. If the second is one-mode, the set of triads considered is only a subset of all mixed triads, and ties in the figure are directed upward; existence of other ties is not considered.

`dyadicCov` returns a named vector, the frequencies of the non-missing non-zero values dc(ego,alter) of the observed or simulated (ego,alter) ties.

`egoAlterCombi` and `egoAlterCovarComb` return a named vector with the frequencies of realized ties for ego-alter combinations as indicated above. The range of `trafo` or `covar`, respectively, should be a subset of the values `0, 1, 2, ..., 9`. Then the name is composed of a number having two digits; the first digit is ego's value, the second alter's value.

`sparseMatrixExtraction` returns the simulated network as a sparse matrix in the `"TsparseMatrix-class"`; this is the virtual class for sparse numeric matrices represented by triplets in the `Matrix` package.
Tie variables for ordered pairs with a missing value for wave=period or period+1 are zeroed; note that this also is done in `RSiena` for calculation of target statistics. Tie variables that are structurally determined at the beginning of a period are used to replace observed values at the end of the period; tie variables that are structurally determined at the end, but not the beginning, of a period are used to replace simulated values at the end of the period.
To treat the objects returned by this function as regular matrices, it is necessary to attach the `Matrix` package in your session.

`networkExtraction` returns the network as an edge list of class `network` according to the `network` package (used for package `sna`). Missing values and structural values are treated as in `sparseMatrixExtraction`, see above.

`behaviorExtraction` returns the dependent behavior variable as an integer vector. Values for actors with a missing value for wave=period or period+1 are transformed to `NA`.

twoeff
# Shorter phases 2 and 3, just for example:

twoalgo <- set_algorithm_saom(nsub=1, n3=50, seed=1291)
(ans <- siena(twodata, effects=twoeff, control_algo=twoalgo,
                returnDeps=TRUE, silent=TRUE, batch=TRUE))
(gof.two <- test_gof(ans, mixedTriadCensus,
                varName=c("onemodenet", "twomodenet"), verbose=TRUE))
plot(gof.two, center=TRUE, scale=TRUE)

## Not run:
### Here come some useful functions for building your own auxiliary statistics:
### First an extraction function.

# igraphNetworkExtraction extracts simulated and observed networks
# from the results of a siena run.
# It returns the network as an edge list of class "graph"
# according to the igraph package.
# Ties for ordered pairs with a missing value for wave=period or period+1
# are zeroed;
# note that this also is done in RSiena for calculation of target statistics.
# However, changing structurally fixed values are not taken into account.
igraphNetworkExtraction <- function(i, data, sims, period, groupName, varName) {
  require(igraph)
  dimsOfDepVar <- attr(data[[groupName]]$depvars[[varName]], "netdims")[1]
  missings <- is.na(data[[groupName]]$depvars[[varName]][,,period]) |
    is.na(data[[groupName]]$depvars[[varName]][,,period+1])
  if (is.null(i)) {
    # test_gof wants the observation:
    original <- data[[groupName]]$depvars[[varName]][,,period+1]
    original[missings] <- 0
```

```
    returnValue <- graph.adjacency(original)
  }
  else
  {
    missings <- graph_from_adjacency_matrix(missings)
    #test_gof wants the i-th simulation:
    returnValue <- difference(
      make_empty_graph(dimsOfDepVar) +
        edges(t(sims[[i]][[groupName]][[varName]][[period]][,1:2])),
      missings)
  }
  returnValue
}

### Then some auxiliary statistics.

# GeodesicDistribution calculates the distribution of non-directed
# geodesic distances; see ?sna::geodist
# The default for \code{levls} reflects that
# geodesic distances larger than 5 do not differ appreciably
# with respect to interpretation.
# Note that the levels of the result are named;
# these names are used in the \code{plot} method.
GeodesicDistribution <- function (i, data, sims, period, groupName,
  varName, levls=c(1:5,Inf), cumulative=TRUE, ...) {

## End(Not run)
```

`test_parameter` *Wald and score tests for RSiena results*

Description

These functions test parameters in RSiena results estimated by `siena`. Tests can be Wald-type (if the parameters were estimated) or score-type tests (if the parameters were fixed and tested).
The function `test_parameter` chooses among the functions `Wald.RSiena`, `Multipar.RSiena`, `testSame.RSiena`, and `score.Test`, based on the input given. The export of the latter three functions is superfluous, but they are kept for backward compatibility.

Usage

```
## S3 method for class 'sienaFit'
test_parameter(x, method=NULL, tested=NULL, tested2=NULL, ...)
```

```
Wald.RSiena(A, x)

Multipar.RSiena(x, tested)

testSame.RSiena(x, e1, e2)

score.Test(x, tested=x$test)
```

Arguments

x	An object of class sienaFit, resulting from a call to siena.
method	NULL, "all", "same", or "score".
tested	One number or a vector of numbers between 1 and p, where p = x$pp, the number of parameters in x excluding the basic rate parameters used for conditional estimation; these indicate the tested parameters. Can also be a logical vector of length p; or, for test_parameter, a k * p matrix.
tested2	A single number or vector as mentioned for tested; these two parameters are tested for equality for method = "same".
A	A k * p matrix, where p = ans$pp, the number of parameters in ans excluding the basic rate parameters used for conditional estimation.
e1, e2	Each an integer number between 1 and p, or a vector of such numbers; the hypothesis tested is that the parameters for effects with number/s e1 are equal to those in e2.
...	Additional arguments (currently not used.)

Details

The tests for test_parameter, Wald.RSiena, Multipar.RSiena, and testSame.RSiena are Wald-type tests (but see below for test_parameter with method=score.
For test_parameter and Wald.RSiena, if tested is a matrix A, the hypothesis tested is $A\theta = 0$, where θ is the parameter estimated in the process leading to x.
For test_parameter and Multipar.RSiena if tested is a number or vector, a multivariate (i.e., simultaneous) test is given of the hypothesis that the parameters mentioned in tested are 0.
For test_parameter if method="all", a test is given of all parameters in the model.
For test_parameter if method="same", the items "tested" and "tested2" should be single numbers or vectors of equal length, and the test of equality of the corresponding two parameters is given.
For test_parameter if method="score", and for score.Test, the parameters with numbers in "tested" should all be used in x as fixed-and-tested parameters, and the multivariate score test of these parameters is given of the hypothesis that the tested parameters have the value indicated in the effects object used for obtaining x.
The numbering of parameters is as in print(x); if conditional estimation was used, numbered as the 'Other parameters').

These tests should be carried out only when convergence is adequate (overall maximum convergence ratio less than 0.25 and all *t*-ratios for convergence less than 0.1 in absolute value).

These functions have their own print method, see `print.sienaTest`.

Value

An object of class `sienaTest`, which is a list with elements:

`chisquare:`	The test statistic, assumed to have a chi-squared null distribution.
`df:`	The degrees of freedom.
`pvalue:`	The associated *p*-value.
`onesided:`	For `df=1`, the onesided test statistic.
`efnames:`	For `Multipar.RSiena` and `score.Test`, the names of the tested effects.

`test_time` *Function to assess and account for time heterogeneity of parameters*

Description

Takes a `sienaFit` object estimated by Method of Moments, and tests for time heterogeneity by the addition of interactions with time dummy variables at waves `m=2...(M-1)`. The test used is the score-type test of Schweinberger (2012).

Tests for joint significance, parameter-wise significance, period-wise significance, individual significance, and one-step estimates of the unrestricted model parameters are returned in a list.
`test_time()` and `sienaTimeTest()` are identical functions. The first name is preferred, the other is kept for backward compatibility.

Usage

```
## S3 method for class 'sienaFit'
test_time(x, effects=NULL,
              excludedEffects=NULL, condition=FALSE, ...)

sienaTimeTest(x, effects=NULL,
              excludedEffects=NULL, condition=FALSE)
```

Arguments

`x`	A `sienaFit` object returned by `siena`.
`effects`	Optional vector of effect numbers to test. Use the numbering on the print of the sienaFit object.
`excludedEffects`	Optional vector of effect numbers for which time heterogeneity is not to be tested. Use the numbering on the print of the sienaFit object.
`condition`	Whether to orthogonalize effect-wise score-type tests and individual significance tests against estimated effects and un-estimated dummy terms, or just against estimated effects.
`...`	For other arguments. Not used currently.

Details

This test follows the score type test of Schweinberger (2012) as elaborated by Lospinoso et al. (2011) by using statistics already calculated at each wave to obtain vectors of partitioned moment functions corresponding to a restricted model (the model in the `sienaFit` object; used as null hypothesis) and an unrestricted model (which contains dummies for waves `m=2...(M-1)`; used as alternative hypothesis).

`condition=TRUE` leads to a rough-and-easy approximation to controlling the mentioned tests also for the unestimated effects.

After assessing time heterogeneity, effects objects can be modified by adding numbers of all or some periods to the `timeDummy` column. This is facilitated by the `includeTimeDummy` function. For an effects object in which the `timeDummy` column of some of the included effects includes some or all period numbers, interactions of those effects with time dummies for the indicated periods will also be estimated.

An alternative to the use of `includeTimeDummy` is to define time-dependent actor covariates (dummy variables or other functions of wave number that are the same for all actors), include these in the data set through `make_data_rsiena`, and include interactions of other effects with ego effects of these time-dependent actor covariates by `set_interaction`. This is illustrated in an example below. Using `includeTimeDummy` is easier; using self-defined interactions with time-dependent variables gives more control.

If you wish to use this function with `sienaFit` objects that use the finite differences method of derivative estimation, or which use maximum likelihood estimation, you must request the derivatives to be returned by wave using `byWave=TRUE` option in the call of `siena07`.

Effects leading to dummy interactions that are collinear with the model originally fitted, after excluding the effects mentioned, will be automatically excluded from the time heterogeneity testing.

If `test_time` gives errors that there are too many collinear effects, run it with a smaller set of effects as specified by the `effects` parameter. For example, if the model has 40 effects of which the first 8 are rate parameters and therefore uninteresting, and there is such an error message, try `effects=9:30`; if that still does not work, decrease the upper limit of 30, if it does work increase it, to find the largest possible set of effects for which heterogeneity assessment still is possible; then as a next step try the remaining effects in a similar way.

Also if the execution is time-consuming, e.g., for a multi-group `sienaFit` object with many groups and many effects, it can be helpful to carry out the function in smaller subsets of effects.

Value

`test_time` returns a list containing many items, including the following:

`JointTest`	A chi-squared test for joint significance of the dummies.
`EffectTest`	A chi-squared test for joint significance across dummies for each separate effect.
`GroupTest`	A chi-squared test for joint significance across dummies; if `sienaFit` is a fit for a multi-group object then these refer to each group; else they refer to each period.
`IndividualTest`	A matrix displaying initial estimates, one-step estimates, and p-values for the individual interactions.

transformScript *Function to transform* RSiena *and* multiSiena *scripts*

Description

Function to transform a script with 'old' function names of RSiena and multiSiena to the new names that are used since version RSiena.1.6.0 and multiSiena.1.2.36.

Usage

```
transformScript(theoldscript, fileName="newScript.R",
                    linelength=80, initialblanks=6, logfile="log.txt",
                    keepOldAlgorithms=FALSE)
```

Arguments

theoldscript	Character vector: an R script which uses RSiena and/or multiSiena.
fileName	Character string naming a file for the new script.
linelength	The maximum line length for the new script.
initialblanks	The number of blanks at the start of each follow-up line for a given transformed R command.
logfile	Character string naming a file, for the log file.
keepOldAlgorithms	Boolean: should the old calls of sienaAlgorithmCreate be retained in the new script, even though they are redundant.

Details

This function transforms theoldscript, supposedly a script with 'old' function names of RSiena and multiSiena, and transforms it to fileName in which the old names are replaced with the new names that are used since version RSiena.1.6.0; the use of the functions is adapted correspondingly.
The calls for constructing the algorithms required for the estimation functions siena and multi_siena are positioned immediately before the calls of the respective estimation functions. This may involve duplication.
For creation of a time-constant dyadic covariate ("coDyadCovar") the argument type=oneMode is always used; the user should check whether, instead, it should be type=bipartite.
This function is not guaranteed to be correct, and the result should be checked!
Hash signs (#) in strings that are names of objects in RSiena functions will lead to errors, because it is assumed that everything following a has sign in a line is not part of the command.
Functions utilizing other RSiena functions may also lead to errors.
If an error is encountered, the end of the log file will show the line number to which the transformation proceeded without errors.
The use of keepOldAlgorithms is just for the sake of possible information or checking. These calls of sienaAlgorithmCreate can be dropped from the new script without any consequences for its functioning.

Note that using "" for a filename will write to the console.

This function transforms calls of RSiena and multiSiena functions to calls utilizing the new names. The only RSiena functions in theoldscript that are executed are calls of sienaAlgorithmCreate; their results are used for transforming calls of siena07 and sienaBayes.

Value

Invisibly, the new script will be returned as a character vector.

update_theta *A function to update the initial values of the parameters, and a function to update an effects object.*

Description

update_theta copies the final values of the parameter estimates for any matching selected effects from a sienaFit object to a Siena effects object.
update_specification includes in a Siena effects object a set of effects that are included in another effects object.
The functions update_theta and updateTheta are identical;
the same holds for update_specification and updateSpecification. The first of these names are preferred, the others are kept for backward compatibility.

Usage

```
## S3 method for class 'sienaEffects'
update_theta(x, prevAns, varName=NULL, ...)
## S3 method for class 'sienaEffects'
update_specification(x, effects.from,
         effects.extra=NULL, name.to=NULL, name.from=NULL, ...)

updateTheta(effects, prevAns, varName=NULL)
updateSpecification(effects.to, effects.from,
         effects.extra=NULL, name.to=NULL, name.from=NULL)
```

Arguments

x	Object of class sienaEffects.
prevAns	Object of class sienaFit as returned by siena07.
varName	Character string or vector of character strings; is this is not NULL, the update will only applied to this dependent variable / these dependent variables.
effects.to	Object of class sienaEffects.
effects.from	Object of class sienaEffects.
effects.extra	Object of class sienaEffects.
name.to	Character string, name of dependent variable in object.to.
name.from	Character string, name of dependent variable in object.from.
effects	Object of class sienaEffects.
...	Additional arguments, not used now.

Details

The initial values of any selected effects in the input effects object which match an effect estimated in prevAns will be updated by update_theta and set to the parameter estimates obtained in prevAns.
If the previous run was conditional, the estimated rate parameters for the dependent variable on which the run was conditioned are added to the final value of theta. If varName is not NULL, this update is restricted to effects for the dependent variable/s specified by varName.
By update_specification, the effects included in effects.from are also included in x (for update_specification) effects.to (for updateSpecification); if name.to and/or name.from is specified, this is restricted to effects for those dependent variables.
If effects.from contains interaction effects, the corresponding main effects will be looked for in effects.from; if they are not found there, they will be looked for in effects.extra. It is not guaranteed that this will be successful. For effects.extra, it is best to use an effects object constructed for the same data set as effects.from, and by the same version of RSiena.

Value

Updated effects object.

Note

Using update_theta explicitly before calling siena rather than using it via the argument prevAns of siena will not permit the use of the previous derivative matrix for option Dolby. In most cases, using siena with prevAns will therefore be more efficient; but sometimes the use of update_theta gives better results.

siena, make_specification

Examples

```
## For updateTheta:
mynet1 <- as_dependent_rsiena(array(c(tmp3, tmp4), dim=c(32, 32, 2)))
mydata <- make_data_rsiena(mynet1)
myeff1 <- make_specification(mydata)
myeff1 <- set_effect(myeff1, transTrip)
myeff1 <- set_interaction(myeff1, list(recip, inPop))
myalgo <- set_algorithm_saom(nsub=1, n3=100, seed=1291)
(ans <- siena(mydata, effects=myeff1, control_algo=myalgo,
                                        batch=TRUE))
ans$theta
```

```
(myeff <- update_theta(myeff1, ans))
##
## For updateSpecification:
myeff2 <- make_specification(mydata)
myeff2 <- set_effect(myeff2, outAct)
update_specification(myeff2, myeff1)
```

---

varCovar *Function to create a changing covariate object.*

Description

This function creates a changing covariate object from a matrix.
It now is superseded by function as_covariate_rsiena.

Usage

```
varCovar(val, centered=TRUE, nodeSet="Actors",  warn=TRUE,
  imputationValues=NULL)
```

Arguments

val	Matrix of covariate values, one row for each actor, one column for each period.
centered	Boolean: if TRUE, then the overall mean value is subtracted.
nodeSet	Character string containing the name of the associated node set. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
warn	Logical: is a warning given if all values are NA, or all non-missing values are the same.
imputationValues	Matrix of covariate values of same dimensions as val, to be used for imputation of NA values (if any) in val. Must not contain any NA.

Details

When part of a Siena data object, the covariate is assumed to be associated with node set nodeSet of the Siena data object. In practice, the node set needs to be specified only in the case of the use of the covariate with a two-mode network.
If there are any NA values in val, and imputationValues is given, then the corresponding elements of imputationValues are used for imputation. If imputationValues is NULL, imputation is by the overall mean value. In both cases, cases with imputed values are not used for calculating target statistics (see the manual).
The value of the changing covariate for wave m is supposed in the simulations to be valid in the whole period from wave m to wave m+1. If the data set has M waves, this means that the values, if any, for wave M will not be used. Therefore, the number of columns can be M or M-1; if the former, the values in the last column will not be used.

Value

Returns the covariate as an object of class "varCovar", in which form it can be used as an argument to make_data_rsiena.

Examples

```
myvarCovar <- as_covariate_rsiena(s50a)
senders <- as_nodeset_rsiena(50, nodeSetName="senders")
receivers <- as_nodeset_rsiena(30, nodeSetName="receivers")
senders.covariate <- as_covariate_rsiena(s50a, nodeSet="senders")
receivers.covariate <- as_covariate_rsiena(s50s[1:30,], nodeSet="receivers")
```

---

varDyadCovar *Function to create a changing dyadic covariate object.*

Description

This function creates a changing dyadic covariate object from an array.
It now is superseded by function as_covariate_rsiena.

Usage

```
varDyadCovar(val, centered=TRUE, nodeSets=c("Actors", "Actors"),
     warn=TRUE, sparse=is.list(val), type=c("oneMode", "bipartite"))
```

Arguments

val	Array of covariate values, third dimension is the time. Alternatively, a list of sparse matrices of type "TsparseMatrix".
centered	Boolean: if TRUE, then the overall mean value is subtracted.
nodeSets	Names (character string) of the associated node sets. If the entire data set contains more than one node set, then the node sets must be specified in all data objects.
warn	Logical: is a warning given if, for non-sparse input, all values are NA, or all non-missing values are the same.

sparse	Boolean: whether sparse matrices or not.
type	oneMode or bipartite: whether the matrix refers to a one-mode or a bipartite (two-mode) network.

Details

When part of a Siena data object, the covariate is assumed to be associated with the node sets named NodeSets of the Siena data object. The names of the associated node sets will only be checked when the Siena data object is created. In practice, the node set needs to be specified only in the case of the use of the covariate with a two-mode network.
The value of the changing covariate for wave m is supposed in the simulations to be valid in the whole period from wave m to wave m+1. If the data set has M waves, this means that the values, if any, for wave M will not be used. Therefore, the number of columns can be M or M-1; if the former, the values in the last column will not be used.

Value

Returns the covariate as an object of class "varDyadCovar", in which form it can be used as an argument to make_data_rsiena.

class(mydyadvar)
```

---

write_report *Function to produce a basic descriptive report of SIENA data sets*

Description

Prints a report of a Siena data object and its default effects.
The functions write_report and print01Report are identical.
The first name is preferred, the other is kept for backward compatibility.

Usage

```
## S3 method for class 'sienadata'
write_report(x, outputName=NULL, ...)

print01Report(data, modelname="Siena", getDocumentation=FALSE)
```

Arguments

x	a Siena data object of class sienadata
data	a Siena data object of class sienadata
outputName	If outputName = NULL and the Siena data set has name dataName, output will be written by write_report to a file with name "dataName_report.txt" in the working directory. If outputName is not NULL, it should be a character string without embedded spaces, and output will be written to a file with name "outputName_report.txt".
modelname	Character string used to name the output file "modelname.txt"
getDocumentation	Flag to allow documentation of internal functions, not for use by users.
...	Additional arguments, not used now.

Details

First deletes any file of the given name, then writes a new one.

Value

No value returned.
