

# Package ‘gensphere’

May 8, 2026

**Type** Package

**Title** Generalized Spherical Distributions

**Version** 1.3

**Date** 2021-01-12

**Author** John P Nolan

**Maintainer** John P Nolan <jpnolan@american.edu>

**Depends** R (>= 3.0), mvnesh, geometry, SphericalCubature (>= 1.5), rgl,  
utils, grDevices, graphics

**Description** Define and compute with generalized spherical distributions - multivariate probability laws that are specified by a star shaped contour (directional behavior) and a radial component. The methods are described in Nolan (2016) <[doi:10.1186/s40488-016-0053-0](https://doi.org/10.1186/s40488-016-0053-0)>.

**License** GPL (>= 3)

**Imports** SimplicialCubature

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2021-01-12 18:20:03 UTC

gensphere-package      *gensphere*

---

## Description

Define and compute with generalized spherical distributions - multivariate probability laws that are specified by a star shaped contour (directional behavior) and a radial component.

## Details

This package implements some classes of generalized spherical distributions in dimensions 2, 3, and above. Functions `cfunc.new`, `cfunc.add.term`, `cfunc.finish` give a flexible way to define a range of shapes for the star-shaped contours. Then function `gensphere` defines a generalized spherical distribution using a contour function and a specification of the radial term. Function `dgensphere` is used to compute the multivariate density  $g(x)$  for  $X$  and function `rgensphere` is used to simulate a sample random vectors with the (approximate) distribution  $X$ .

A large class of distribution can be described as generalized spherical laws. In particular, all isotropic/radially symmetric distributions and all elliptically contoured distributions are generalized spherical laws. Such distributions can be represented as:  $\mathbf{X} = R\mathbf{S}$  where  $R$  is a positive random variable and  $\mathbf{S}$  is a random vector distributed uniformly (with respect to surface area) on the contour, see Nolan (2015).

Throughout this package, points in  $d$ -dimensional space are represented as column vectors; this is different than what base `R` and packages `mvmesh`, `geometry`, etc. use; but it is the same as package `SphericalCubature`, `SimplicialCubature`, and other packages.

This research was supported by an agreement with Cornell University, Operations Research & Information Engineering, under contract W911NF-12-1-0385 from the Army Research Development and Engineering Command.

Please let me know if you find any mistakes. I will try to fix bugs promptly. Constructive comments for improvements are welcome; actually implementing any suggestions will be dependent on time constraints.

Version 1.0 was released on 18 May 2016. Version 1.1 was released on 13 September 2017 and includes a new optional argument `norm.const.method` in the function `cfunc.finish`. Also changes were made to accomodate changes in package `SphericalCubature`.

Version 1.2 (never on CRAN, 10 January 2021) has a minor change to work with the update of package `SphericalCubature` to version 1.5, updated a reference, and the examples include `if(interactive())` around calls to plotting functions. Version 1.3 (12 January 2021) adds links to the DOI for the paper this work is based on, and provides a faster 3-d example.

cfunc.new

*Define and evaluate a contour function*

---

## Description

The directional part of a generalized spherical distribution is defined by a contour function, cfunc for short. These functions are used to define a contour function and then evaluate it.

## Usage

```
cfunc.new(d)
cfunc.add.term(cfunc, type, k)
cfunc.finish(cfunc, nsubdiv = 2, maxEvals=100000, norm.const.method="integrate", ...)
cfunc.eval(cfunc, x)
```

## Arguments

d	dimension of the space
cfunc	an object of class "gensphere.contour"
type	string describing what type of term to add to the contour
k	a vector of constants used to specify a term
x	a (d x n) matrix, with columns x[,i] being points in $R^d$
nsubdiv	number of dyadic subdivisions of the sphere, controls the refinement of the tessellation. Typical values are 2 or 3.
maxEvals	maximum number of evaluations of the integrand function, see details section below
norm.const.method	method used to compute the norming constant. Can be "integrate" (the default, in which case the contour function is numerically integrated to get the norming constant), or "simplex.area" (in which case no integration is done; the surface area of the contour is approximated by the surface area of the tessellation). This

later choice is for complex surface or higher dimensional surfaces where the numerical integration may fail or take a very long time. This allows simulation in cases where the numerical integration is not feasible.

... optional arguments to pass to integration routine, see details section below

## Details

A contour function describes the directional behavior of a generalized spherical distribution. In this package, a contour function is built by calling three functions: `cfunc.new` to start the definition of a  $d$ -dimensional contour, `cfunc.add.term` to add a new term to a contour (may be called more than once), and `cfunc.finish` to complete the definition of a contour.

When adding a term, `type` is one of the literal strings "constant", "elliptical", "proj.normal", "lp.norm", "gen.lp.norm", or "cone". The vector `k` contains the constants necessary to specify the desired shape. `k[1]`=the first element of `k` is always a scale, it allows one to expand or contract a shape. The remaining elements of `k` depend on the value of 'type':

- "constant": `k` is a single number; `k[1]`=radius of the sphere
- "elliptical": `k` is a vector of length  $d^2+1$ ; `k[1]`=scale of ellipse, `k[2:(d^2+1)]` specify the symmetric positive definite matrix `B` with is used to compute the elliptical contour
- "proj.normal": `k` is a vector of length  $d+2$ ; `k[1]`=scale of the bump, `mu=k[2:(d+1)]` is the vector pointing in the direction where the normal bump is centered, `k[d+2]`=standard deviation of the isotropic normal bump
- "lp.norm": `k` is a vector of length 2; `k[1]`=scale and `k[2]`=`p`, the power used in the `lp` norm
- "gen.lp.norm": `k` is vector of length  $2+m*d$  for some positive integer `m`; `k[1]`=scale, `k[2]`=`p`, the power used in the `lp` norm, `k[3:(2+m*d)]` specifies a matrix `A` that is used to compute  $\|A x\|_p$
- "cone": `k` is a vector of length  $d+2$ , `k[1]`=scale, `mu=k[2:(d+1)]`= the center of the cone, `k[d+2]`=base of the cone

Note that `cfunc.finish` does a lot of calculation, and may take a while, especially in dimension  $d > 2$ . The most time consuming part is numerically integrating over the contour, a  $(d-1)$  dimensional surface in  $d$ -dimensional space and in tessellating the contour in a way that focuses on the bulges in the contour from cones and normal bumps. The integration is required to calculate the norming constant needed to compute the density. This integration is performed by using function `adaptIntegrateSphereTri` in **SphericalCubature** and is numerically challenging. In dimension  $d > 3$  or if `nsubdiv > 4`, users may need to adjust the arguments `maxEvals` and ... The default value `maxEvals=100000` workw in most 3 dim. problems, and it takes a few seconds to calculate. (For an idea of the size and time required, a  $d=4$  dim. case used `maxEvals=1e+7` and took around 5 minutes. A  $d=5$  dim. case used `maxEvals=1e+8`, used 160167 simplices and took over 2 days.) Note that this calculation is only done once; calculating densities and simulating is still fast in higher dimensions. It may be useful to save a complicated/large contour object so that it can be reused across R sessions via `save(cfunc)` and `load(cfunc)`.

Note: the first time `cfunc.finish` is called, a warning message about "no degenerate regions are returned" is printed by the package **geometry**. I do not know how to turn that off; so just ignore it.

`cfunc.eval` is used to evaluate a completed contour function.

**Value**

cfunc.new and cfunc.add.term return a list that is an incomplete definition of a contour function. cfunc.finish completes the definition and returns an S3 object of class "gensphere.contour" with fields:

d	dimension
m	number of terms in the contour function, i.e. the number of times cfunc.add.term was called
term	a vector length m of type list, with each list describing a term in the contour function
norm.const	norming constant
functionEvaluations	number of times the integrand (contour) function is evaluated by adaptIntegrateSphereTri when computing norm.const
tessellation	an object of type "mvmesh" that gives a geometrical description of the contour. It is used to plot the contour and to simulate from the contour
tessellation.weights	weights used in simulation; surface area of the simplices in the tessellation
simplex.count	vector of length 3 giving the number of simplices used at the end of three internal stages of construction: after initial subdivision, after refining the sphere based on cones and bumps, and final count have adaptive integration routine partitions the sphere
norm.const.method	value of input argument norm.const.method

cfunc.eval returns a vector of length  $n = \text{nrow}(x)$ ;  $y[i] = \text{cfunc}(x[,i]) = \text{value of the contour function at point } x[,i]$ .

The plots below show the three contours defined in the examples below.

ball with bump with 576 simplices

### Examples

```

# 2-dim diamond
cfunc1 <- cfunc.new(d=2)
cfunc1 <- cfunc.add.term( cfunc1,"lp.norm",k=c(1,1))
cfunc1 <- cfunc.finish( cfunc1 )
cfunc1
cfunc.eval( cfunc1, c(sqrt(2)/2, sqrt(2)/2) )
if( interactive() ) { plot( cfunc1, col='red', lwd=3, main="diamond contour" ) }

# 2-dim blob
cfunc2 <- cfunc.new(d=2)
cfunc2 <- cfunc.add.term( cfunc2,"constant",k=1)
cfunc2 <- cfunc.add.term( cfunc2,"proj.normal",k=c( 1, sqrt(2)/2, sqrt(2)/2, 0.1) )
cfunc2 <- cfunc.add.term( cfunc2,"proj.normal",k=c( 1, -1,0, 0.1) )
cfunc2 <- cfunc.finish( cfunc2, nsubdiv=4 )
if(interactive() ) {
  plot( cfunc2, col='green', lwd=3, main="contour with two bumps" )
}

# 3-dim ball with one spike
cfunc3 <- cfunc.new( d=3 )
cfunc3 <- cfunc.add.term( cfunc3, "elliptical",k=c( 1, 1,0,0, 0,1,0, 0,0,1 ) )
cfunc3 <- cfunc.add.term( cfunc3, "proj.normal",k=c( 1, 1,0,0, .25 ) )
cfunc3 <- cfunc.finish( cfunc3, nsubdiv=3 ) # takes ~20 seconds, get warnings
plot( cfunc3, show.faces=TRUE, col='blue' )
nS <- dim(cfunc3$tessellation$S)[3]
title3d( paste("ball with bump with",nS,"simplices") )
}

```

---

gensphere

*Generalized spherical distribution definition, density, simulation*

---

### Description

Define a generalized spherical distribution by specifying a contour function, a radial density function, a radial simulation function, and a value of the density at the origin. Once it is defined, compute density and simulate that distribution.

### Usage

```
gensphere(cfunc, dradial, rradial, g0)
dgensphere(x, gs.dist)
rgensphere(n, gs.dist)
```

### Arguments

cfunc	contour function object defined by <code>cfunc.new</code> , <code>cfunc.add.term</code> and <code>cfunc.finish</code>
dradial	a function to evaluate the density for the radial component of distribution
rradial	a function to simulate values of the radial distribution
g0	$g(0)$ = value of the multivariate density at the origin
x	(d x n) matrix of point where the density is to be evaluated. Columns <code>x[,i]</code> are vectors in d-space
gs.dist	a generalized spherical distribution, an object returned by function <code>gensphere</code>
n	number of values to generate

### Details

A generalized spherical distribution is specified by calling function `gensphere` with the contour function (defined via function `cfunc.new`, `cfunc.add.term` and `cfunc.finish`), a function to compute the density of the radial term `R`, a function to simulate from the radial term `R`, and  $g(0)$ =the value of the density at the origin. See the general representation of generalized spherical laws in [gensphere-package](#).

If the distribution is `d` dimensional and the radial term is a gamma distribution with `shape=shape` and `scale=1`,  $g(0)=0$  if `d < shape`,  $g(0)=cfunc\$norm.const$  if `d=shape`,  $g(0) = \infty$  if `d > shape`. In general,  $g(0) = \lim_{r \rightarrow 0^+} r^{1-d} dradial(r)$ .

### Value

`gensphere` returns an S3 object of class "gensphere.distribution" with components:

cfunc	a contour function defined with <code>cfunc.new</code> , etc.
dradial	a function that evaluates the density of the radial component
rradial	a function that simulates values of the radial component
g0	$g(0)$ , the value of the multivariate density $g(x)$ at the origin

`dgensphere` returns a numeric vector  $y$  that contains the value of the density of  $\mathbf{X}$ :  $y[i]=g(x[i])$ ,  $i=1,\dots,n$ . Note that  $g(x)$  is the density of the vector  $\mathbf{X}$ , whereas  $dradial$  is the denis of the univariate radial term  $R$ .

`rgensphere` returns a  $(d \times n)$  matrix of simulated values of  $\mathbf{X}$ . Note that these values are an approximation to the distribution of  $\mathbf{X}$  because the contour is approximated to a limited accuracy in `cfunc.finish`.

Here are plots of the density surface and simulated points generated by the examples below.

### Examples

```
# define a diamond shaped contour
cfunc1 <- cfunc.new(d=2)
cfunc1 <- cfunc.add.term( cfunc1,"gen.lp.norm",k=c(1,1,2,0,0,1))
cfunc1 <- cfunc.finish( cfunc1 )
cfunc1

# define a generalized spherical distribution
rradial <- function( n ) { rgamma( n, shape=2 ) }
dradial <- function( x ) { dgamma( x, shape=2 ) }
dist1 <- gensphere( cfunc1, dradial, rradial, g0=cfunc1$norm.const )
dist1

# calculate density at a few points
dgersphere( x=matrix( c(0,0, 0,1, 0,2), nrow=2, ncol=3), dist1 )

# simulate values from the distribution
x <- rgensphere( 10000, dist1 )

# calculate and plot density surface on a grid
xy.grid <- seq(-3,3,.1)
if( interactive() ) {
  z <- gs.pdf2d.plot( dist1, xy.grid )
}
```

```

    title3d("density surface")
    plot(t(x),xlab="x",ylab="y",main="simulated points")
}

```

---

genspheremisc	<i>Miscellaneous functions used in working with generalized spherical laws</i>
---------------	--

---

## Description

Miscellaneous internal functions for the gensphere package.

## Usage

```

gs.cone(x, mu, theta0)
gs.elliptical(x, B)
gs.gen.lp.norm(x, p, A)
gs.lp.norm(x,p)
gs.proj.normal(x, mu, sigma)
gs.vfunc.eval(cfunc, x)
gs.pdf2d.plot(gs.dist, xy.grid = seq(-10, 10, 0.1) )
RefineSphericalTessellation(V1, V2)
NearbyPointsOnSphere(x, epsilon)
RotateInNDimensions(x, y)
## S3 method for class 'gensphere.contour'
print(x,...)
## S3 method for class 'gensphere.distribution'
print(x,...)
## S3 method for class 'gensphere.contour'
plot(x,multiplier=1,...)

```

## Arguments

x, y	vectors representing points in d-dimensional space
mu	direction of the mode for a cone/normal bump
theta0	angle between peak of the cone and the base of the cone
B	(d x d) positive definite shape matrix
A	matrix used to compute $\ A x\ _p$
p	power of the $l^p$ norm; $p=2$ is Euclidean distance
gs.dist	object of class "gensphere.distribution" defined by gensphere
xy.grid	a matrix of (x,y) values in 2-dimensions
cfunc	an object of class "gensphere.contour" defined by cfunc.new, etc.
...	optional arguments to the 2-dimensional plot, e.g. col='red', etc.

<code>sigma</code>	scale parameter for a normal bump
<code>epsilon</code>	vector of positive numbers where there are points added around a particular direction
<code>V1, V2</code>	matrices of vertices which are joined together to get a refinement of the grid
<code>multiplier</code>	a positive number used to scale the contour

**Details**

These are undocumented functions that are used internally. The functions `gs.cone`, `gs.elliptical`, `gs.gen.lp.norm`, `gs.lp.norm`, `gs.proj.normal`, `gs.vfunc.eval` are used in evaluating a contour function. `RefineSphericalTessellation`, `NearbyPointsOnSphere` are used in defining the tessellation of the contour that identifies bumps and cones. `gs.pdf2d.plot` and the `plot/print` methods are initial attempts at plotting and printing a summary of objects.

These functions may change or disappear in the future.
